HE OPERATIVE TREATMENT OF SIMPLE FRACTURES*

A. F. JONAS, M.D.
OMAHA, NEB.

The treatment of simple fractures by the open opera- e procedure has gained much in favor *during the last* w years. In spite of the fact that surgeons have occu- d themselves much in the study of this branch of gery, *perfection has not been attained and the con-* versy still continues. Among practical surgeons of ge experience direct fixation appliances in compound ractures, where the bones are exposed, when they can- ot be kept in position by splints, have come into gen- al use. There seems to be a general unanimity of pinion that such is the best practice. But when the atter of simple fractures is presented for considera- on there is a lack of uniform opinion.

In this connection I shall draw from my own personal perience, gathered from a rather extensive service of cident surgery, extending *over a period of upwards* twenty-five years. There will be no tabulation of ases and no review of the literature, but in a brief and eneral way there will be a summary of observations d experiences regarding the management of simple ctures with special reference to the open operation d direct fixation.

CONSIDERATIONS IN REGARD TO THE OPEN METHOD

When we consider the extreme difficulty, and, in ny cases, the absolute impossibility of effecting an urate adjustment of fractured bones by manipula- n, and the uncertainty of fixing and maintaining the ken ends in perfect alignment, it would seem that must instantly and unhesitatingly decide in favor open treatment and the employment of such mechan- al devices as will positively hold in perfect position fractured bone. That this is the ideal method is ond dispute. All are agreed that, while this method ideal, it also becomes necessary that the work be done der ideal conditions, which means a perfect control asepsis, and unusual mechanical and operative skill the part of the surgeon. Any lapse in aseptic detail *more fatal to perfect union and perfect final results n a similar error in technic in abdominal* surgery, r here the lymphatics are less able to cope with ordi- ry infections than in the peritoneal cavity. In no her domain of surgery are errors in asepsis so often *nished* by failure. To accomplish these results, ined assistants and a faultless operating equipment e essential.

It at once becomes evident that it is necessary to *vide our simple fracture cases requiring treatment* into two groups: first, those that can be treated in a hospital, which comprises a small group; second, those that must be treated outside the hospital, and comprises by far the larger group.

The greater number of fractures always have been and always will be treated by the general *practitioner.* His functional results are usually good, and satisfactory to the patient, even though a skiagram would show imperfect alignment and defective adjustment. Consequently, the surgeon can never hope to attain an exclusive control of the management of fractures and the *open treatment can never become the universal treatment.*

Now, would it be desirable to do an open operation in all simple fractures? This we must answer in the negative, because many of them can be accurately and perfectly adjusted by manipulations and accurately held in place by proper retentive dressings. A Colles fracture of the wrist can nearly always be reduced if the fragments, which are often impacted, are unlocked by increasing the deformity before an attempt at replacement is made. In a Pott fracture of the ankle-joint *the bones often return to their normal position with a* snap if traction is made in the line of deformity before a reduction of the fracture is attempted, and the bones *are easily* held in position. Many transverse fractures of the tibia, and supracondyloid fractures of the femur, show very little tendency to displacement when once *properly reduced and the extremity secured in a well* fitting plaster-of-Paris cast. Therefore the most enterprising surgeon would hardly find justification for a statement that all simple fractures must be exposed by a free incision and the broken bones secured by suture or a mechanical device. Those of us who had an opportunity of examining Arbuthnot Lane's numerous skiagrams of simple fractures, on which operation had recently been done, which he exhibited before us a year ago, could not help but be impressed with the fact that some of his cases would have done quite as well if the fractures had been reduced by manipulation and the use of the same external splints that he employed to reenforce the clips and screws which he used through an incision. Experience has shown that with the open operation the external retentive and fixation appliances must be of the same design and must be applied with the same care as in cases where no open incision is made.

PHYSIOLOGIC SOFTENING OF BONE ENDS

At best, fixation appliances used to secure accurate adjustment in the open incision can be depended on only for a few days, because *the bony structure immediately* surrounding a screw or peg or wire introduced in the bone becomes loose and fails to hold in accurate apposition bone fragments unless aided by a carefully applied external splint. I had observed many years ago in cases of fracture that could not be held in good apposition, where a resort to an open incision became necessary, that after a lapse of a week or two the fractured ends rapidly underwent a process of softening. When the case came to immediate operation the bony structure was unchanged, but if the operative interference was delayed for a week or more, the fractured ends had sometimes become so soft that the bone drill could almost be forced through the bone by pressure. It was thought that this condition was pathologic and peculiar to some individuals only. These observations were used as a basis to account for non-union in bones believed otherwise to be well adjusted. I learned, however, after I had become more familiar with skiagraphic findings, that a certain amount of bone softening after fractures is physiologic. The *x*-ray shadow depends on the amount of inorganic matter present in the bone. This inorganic matter is made up of phosphate, carbonate and fluorid of calcium and a small amount of phosphate of magnesium, altogether about 67 per cent. in the normal bone. The density of the shadow seems to depend chiefly on the calcium salts (64 per cent.).

---

* Read in the Section on Surgery of the American Medical Asso- tion at the Sixty-first Annual Session, at St. Louis, June, 1910.

It was observed that when a succession of skiagrams were made at intervals of several days in given cases of fracture, in each succeeding skiagram the shadow at the seat of fracture became less dense, and in one or two instances it almost disappeared. I did not at first fully appreciate the full significance of the dim shadow—not until several cases were observed in which the broken ends were so widely separated that an open operation became inevitable, and in all these cases there was an amount of softening which was in direct proportion to the time that had elapsed after the fracture. This decreasing density of the *x*-ray shadow has been observed in nearly all fractures, whether reduced or not, in which I have obtained skiagrams. The bone seems to respond promptly to traumatisms. The relative proportion of lime salts become disturbed at once, and their disappearance can be noted early. This condition of bone rarefaction, while peculiar to bone fractures, and part of the reparative process, has also been noted and described by E. R. Corson[1] as bone atrophy. He points out the fact that the bone terminals become atrophied in the presence of many chronic diseases, a process which may or may not be pathologic.

In fractures, however, we must consider these bone changes as a necessary physiologic process. While the skiagraphic observations are of recent date, the state of softening of fractured bone-ends, the multiplication of the periosteal cells, the changes in the marrow, Haversian canals and lacunæ, the development of a mass of granulations between the fractured ends and extending into the bones themselves, have for a long time been common knowledge. But this process has not always been taken into consideration by the operating surgeon, who would wire or nail or screw together all broken bones at any time or stage. In my own work I learned after several failures, that mechanical devices applied directly to the bones during the stage of active physiologic softening are often ineffective in maintaining necessary coaptation. Consequently I attempt to satisfy myself at once whether fractured bones can be adjusted manually and secured by external appliances. If this can be done, the case is treated by the closed or non-operative method. Should it be found that reduction cannot be accomplished in the usual way, or that coaptation cannot be maintained, the open or operative method is at once resorted to before the bones have undergone reparative softening.

INTERNAL FIXATION DEVICES SHOULD BE USED EARLY

At this early stage any mechanical device applied directly to the bone will maintain a position sufficiently long for all the parts concerned to adapt themselves to a correct position. That screws and wires do not maintain a firm hold until bony union is complete has bee shown in all cases in which it became necessary, eithe early or late, to remove them. All devices were perfectly loose. The lime salts in immediate contact wit all foreign bodies become absorbed so that their firm hold is lost. Consequently we can expect a maintenance of good position only until the reparative proces is fairly under way. The greatest difficulty to overcome in fractures of long bones is muscular rigidity Screws or wires, properly applied, will hold firmly until the muscular spasm is allayed. Usually wit muscular relaxation, which occurs in five to eight days in cases of immediate operation, the tendency to overlapping and angulation is arrested. Therefore, if w can secure good coaptation until the chief factors f displacement cease to be operative, we will achieve good result. Several of the many mechanical devic will do this if applied early while the bones are sti hard. Consequently it was soon learned that if an ope operation is to be done, it should be done immediately.

It was found that when an open operation was attempted in from two to three weeks after injury in cases of fracture of the femur with overlapping, it was difficult and often impossible to overcome the muscular contraction. The same was found to be true in fractures of the bones of the leg, the arm and the forearm. It sometimes became necessary to do tenotomies an myotomies, which are not always advisable or practicable, especially in the thigh. Consequently I attempte in all cases to determine as early as possible if the fracture could be adjusted manually and adjustment maintained by external splints. If there was a tendency to recurrence of displacement or an impossibilit to correct misplacement, an open operation was do as soon as the patient could be brought into a favorable environment, which meant a hospital.

DETERMINING APPOSITION

In recent fractures of the forearm it was found p sible in some cases to manipulate the extremity whi being viewed through a fluoroscope until it was asc tained whether or not good apposition was possible. reduction was successful, the forearm was fixed w such splints as maintained correction. If I did not succeed in securing fair apposition of the fractured end and a good functional result was improbable, an ope operation was resorted to.

The same procedure was found practicable in fr ture of the humerus, a bone in which non-union is more frequent outcome than in any other. It has be asserted that non-union of the humerus is most f quently due to non-adjustment; that means that n sufficient manipulative efforts are made to secure prop reduction. Too often the attendant is satisfied to app his dressing without assuring himself that there is a end-to-end approximation of the broken fragments. I my work I do not rest content until actual crepitati can be obtained, in order that I may know that muscle, fascia or loose fragment of bone is interpos between the fractured ends. General anesthesia is sorted to in all cases in which manipulation is too pai ful or muscular rigidity marked. While it may *true that non-union is due to defective innervation, di* cases of the bone, syphilis or excessive rarefication, we must admit that a defective relation of the fragments is the prime factor for consideration. With an increasing experience I am inclined to believe that in all fractures of the humerus, and, I may add, of the femur also, general anesthesia is necessary, not only in bad displacements, but in those of very limited, or even no primary displacement. I have observed several cases in healthy and vigorous young persons, in which there existed little or no displacement and in which immobilization was easy and complete, that ended in non-union, due, no doubt, to a restricted local reaction, a defective hyperemia. The nutritive and reparative process was too slight or too short. To insure a sufficient local reaction, vigorous friction of the fragments was made by rubbing the ends on each other in cases in which there was no local swelling or hematoma. It was found that the fluoroscope was useful, in showing when reduction was secured. If it was shown that reduction was impossible or if I failed to secure distinct crepitus, an open operation was done.

---

RECENT PRACTICE

For the last fifteen years all patellar fractures have been opened and wired. Since it was shown how constantly large portions of fascia were crowded between the fragments in all cases, a free transverse incision, a clipping away of all torn fascia, an accurate approximation and a securing of the fragments with wire or chromic gut, has been the practice.

The immediate reduction and fixation of overlapped fractured clavicles with silver plates and screws has become more frequent.

Fractures of the cranium, whenever accessible, have always even in the preantiseptic era, been treated by operation.

In personal work I have drifted between the two extremes. Before the mastery of antiseptics had been achieved, all open operations were feared. Only in depressed fractures of the skull and in some compound fractures was it the custom to attack the bones directly. The fear of converting a simple and non-infected fracture into an open and possibly an infected one, was so great that rather than create an infected compound fracture, one was willing to take chances on obtaining a fairly good functional result even though the fluoroscope of to-day would have indicated imperfect apposition. All simple fractures were "set" by hand, as well as possible, and retained with what was regarded as a proper and suitable dressing in all cases.

Then with the advent of the Roentgen ray good functional results were not considered sufficient, but it was insisted by many that the bones must always be brought into perfect alignment. It was urged that no longer could the surgeon bury his mistakes, for the *x*-ray never failed to reveal his errors in "bone-setting." Therefore, we drifted along with the tide of surgical sentiment and began wiring all fractures. When my enthusiasm had somewhat abated and I recalled what I had known before, that many fractures had been reduced and easily secured by the closed method, showing that a large number of operations were useless and had not added to a more perfect outcome. Then when I recalled the cases in which operation had been done under an imperfect environment and in which infection had supervened, and, of course, improvement had not resulted therefrom, I receded from my extreme position and reduced the problem to simple rules which are now the guide. They are as follows:

RULES TO BE FOLLOWED

1. All fractures that can be adjusted manually and can be fixed in a position that will insure a good functional result, even though the Roentgen rays indicate a lack of perfect end-to-end approximation, are to be treated by the closed method.
2. In all fractures with a marked deformity, such as overlapping, angulation, lack of contact of fractured surfaces, when it is apparent that union will not take place, an open operation is done.
3. In all cases in which there is an interposition of soft structures or loose bone fragments, an open operation must be done.
4. All compound fractures are treated by operation if the broken ends do not fall into easy apposition.
5. All depressed cranial fractures are cases for an open operation.
6. All spinal fractures showing symptoms of compression are cases for an open operation.

The Roentgen ray must be employed whenever possible to aid in a proper estimation of the extent and location of the fracture. It must determine for us whether bone approximation is sufficient after the fixation appliance, internal or external, has been applied.

Having determined at the earliest possible moment that manipulation is fruitless to replace the broken bones, an immediate operation should be done before the physiologic rarefying process has begun, or at least before it is very far advanced.

FIXATION MATERIALS AND APPLIANCES

During the last twenty years I have run almost the entire list of mechanical contrivances to secure accurate adjustment of fractures. The earliest experience was with silver wire. The chief objection to this material was found to be its liability to break. Often, after a prolonged operation, when accurate approximation had been obtained, and an accidental movement on the part of the assistant was made while the external splint was being applied, a distinct snapping of the wire could be felt and heard. Occasionally the wire broke after the dressing was complete, but was not discovered until an operation for non-union disclosed a broken wire. Iron wire proved to be no better. Then a change to bronze-aluminum wire was made. This material possesses a tensile strength four times that of silver, and left little to be desired so far as strength was concerned, but it was often difficult to secure and maintain apposition of the broken ends. No matter how ingeniously the wire was placed, partial displacement was the rule rather than the exception.

In several instances silkworm gut, several strands twisted, were used. The tensile strength was sufficient, but displacement could not always be prevented. Chromic gut lacked certainly of strength and its durability was uncertain.

Nails were used a number of times in oblique fractures of the tibia, but became too loose to maintain accurate apposition until bony union was complete. The same observations were made with screws that were made to pass through the bone.

Once I inserted a bone fragment that had been split off and lay loose near the seat of fracture into the medullary canal of the broken ends of a femur. This was reinforced by a bronze wire. The outcome was good. Volkmann treated a united fracture of a femur in a child by inserting into the medullary canal a piece of fresh bone taken from an amputated limb.

In one case an ivory peg in the medullary canal was used to fix an oblique fracture of the tibia. Bony union was good, but it became necessary to remove the peg later. Neither the solid ivory cylinder of Bircher nor the interosseous splint of Senn were ever employed. Gluck's work with ivory joints showed that the absorptive capacity of the tissues was inadequate to cope with such masses of foreign material.

In several instances good union was achieved with Senn's bone ferrule, but it became necessary to remove them, and their removal was not an easy task.

Parkhill's clamps did service in about a half dozen cases, but they were awkward and clumsy and danger of infection was much greater than with simpler appliances.

Finally, metallic plates, applied by means of screws directly to the bone, came up for consideration. At first steel plates similar to those now used by Lane of London were employed. It was found that the plates were so firm and unyielding that if the slightest bend occurred at the seat of fracture while the fixation dressing was being applied, the screws at one end of the plate were partially pulled out and a partial displacement of the bones occurred. The fragments, instead of being firmly fixed, sometimes became loose. This was true in fractures of the femur.

I then became acquainted with the silver bar or plate of Sick, and in this have found a material that seems to be of practical utility and free from many objections found in most other appliances. This material is obtained in bars about 12 inches in length, ½ inch in width and ⅛th inch in thickness. It contains numerous drill holes for screws. It can be cut in any length to suit a given fracture. It is sufficiently pliable to adapt itself to any inequality of the bone and possesses enough flexibility so that any accidental movement at the point of fracture does not break the plate nor loosen its screws. Should it require removal later, as most bone fixation appliances do, it is a simple operation. The plate and screws are found perfectly loose and can be removed through a short incision.

SOME DETAILS OF TECHNIC

I have endeavored to reduce my methods and technic to a state of simplicity. Nothing is introduced into the open wound that has touched the skin. Finger contact is avoided. All parts of the wound are handled with sterile instruments. In all cases in which an open operation is found necessary, three forms of material are used to insure bone coaptation, viz.: the silver plates of Sick, bronze-aluminum wire, and chromic gut, the latter only to reinforce the metallic appliance.

Brandeis Building.

ABSTRACT OF DISCUSSION

DR. E. WYLLYS ANDREWS, Chicago: The old habit of treating fractures by the closed method is so mixed with the newer method, the open treatment, that it is difficult to obtain a clear impression of what the surgery of fractures is to be in the future. If there were a man whose practice had been entirely operative, and who did not know anything about the surgery of the last 2,000 years, who knew nothing of the mechanical treatment of bone lesions, he would unquestionably evolve a system of cutting operations. It would differ radically from what we have inherited. We seem to be standing at the parting of the ways and I do not think that any one of us can tell whether it is going to lead us to the universal adoption of the open method, or to a combination of methods. The greater must include the less, however. At the present time we operate in every case of fractured patella in a normal subject with the associated danger of infection, loss of joint function, ankylosis, and possibly death. Is it not reasonable to suppose that in the presence of the lesser dangers in fractures not involving the larger joints the open method is the better and much to be preferred? We have in the Lane plates the best mechanical device for securing and restoring continuity of normal bone absolutely. A half cylinder of aluminum fitting the contour of the shaft of the bone and perforated with holes is the best appliance we have, one which has almost revolutionized the treatment of fractures of the femur, in my practice at least.

In no class of fractures are we confronted with a more difficult mechanical problem than with simple fractures of the femur. The bone is not large and the muscles are large and strong, therefore, the results from the closed method of treatment are often disappointing. Why not operate as a routine, as in a case of fracture of the patella? Repair is more speedy and the result is excellent in from four to six weeks as *against eight or ten in the old way*.

DR. HERMAN E. PEARSE, Kansas City, Mo.: In the open treatment of fractures I have found it necessary to operate about once in five cases, and most frequently in cases of fractures near the shoulder joint, near the knee, and near the ankle. I have used the method in simple fractures and in the early compound fractures, also in the very badly infected compound fractures. There is only one point in regard to which I wish to differ with Dr. Jonas, and that is as to the reduction of the bone and its consequences on the fracture. The bone is a crystallization in the tissues of lines of force, and bone atrophies from non-use whenever forces are not applied to the shaft, just as a muscle atrophies when motion is taken away. Therefore, if you bring the ends of a broken bone together under the most careful asepsis, so that there is no further oozing, and then thoroughly fix the fragments by means of internal splints, putting on only such retentive apparatus as will serve to protect the bone for the time being, and then allow the patient more or less use of the arm or leg or hand, you will not have the consequent rarefaction of bone, at least not to the degree that I have been able to ascertain by means of the Roentgen ray.

This brings us to the tremendous value of that procedure, and to the consideration of what Dr. Andrews said, that we are at *the parting of the ways. While now I operate but* once in five times, and then only in the unfavorable cases, had I the support of my own conscience and of public sentiment, I am sure that I would do away with the rarefaction of bone which comes from non-use, because, as I said, the bone is only the crystallization of lines of force applied in its use. I have seen the radiogram of a splint taken twelve years after its application, in the leg of a teamster. There were no ill results whatever in contour, size and shape of the bone were perfect, and there was no interference whatever with the function of the leg.

DR. JERE L. CROOK, Jackson, Tenn.: The very excellent paper by Dr. Jonas will no doubt call to mind the interesting symposium on this subject before this section last year led by Mr. Lane, of London. Mr. Lane said that an operation should be performed in every case of fracture, whether simple or compound. The consensus of opinion at the close of the discussion was just about what Dr. Jonas gave us to-day. Dr. Andrews says that we are standing at the parting of the ways. That is true, to a certain extent, but the subject of the treatment of fractures is one which should be discussed from the standpoint of the men who render first aid—that is, the general surgeon's standpoint. It is different in the practice of the surgical specialist. He does not have the opportunity to demonstrate his ability except in rare instances when a patient limps into his office—a crippled exponent of inefficient surgery—having been sent by the man who gave first aid and who is anxious to avoid the annoyance of a malpractice suit.

In every compound fracture, there is already a solution of continuity, and it will not add anything to the danger of sepsis or the probability of death if we treat that fracture by the open method, simply enlarging the wound already produced. We can then determine quickly and accurately what the nature of the fracture is, whether there is any interposition of muscles or ligaments, whether any blood-vessels have been torn, and we can remedy all these things, with the expectation of getting a good result afterward. Three cases under my observation at the present time have demonstrated the value of this method. In each of these cases the anterior tibial artery was cut, there was interposition of the muscular structures, and good results simply would not have been possible, except by the open method. The duration of the cases was from three to six months; the patients progressed well and made a complete recovery.

The man who renders first aid has it in his hands to produce favorable or unfavorable results. It is, therefore, incumbent on such men to use the most rigid asepsis, and be prepared to perform the operation where it is indicated; and this can be done in practically every country house, if we are careful and appreciate what asepsis means.

Dr A. F. Jonas, Omaha: In my opinion, all simple fractures will never be treated by the open method for the reason that the operative technic must be in accordance with perfect aseptic surroundings, with trained assistants and proper appliances. Those who have seen Lane operate speak especially of his aseptic technic, which is absolutely faultless. He does not introduce his finger into the wound at any time nor any instrument that has touched the skin or any thing that is of doubtful asepsis. Therefore, he has ideal results. Those of us who have had to operate much in private houses as well as in hospitals know how inadequate are the means at our command in the former; if we fail in any part of the aseptic procedure, union may be imperfect and conditions are worse than they would have been if we had treated the case by the non-operative method.

We have run the entire list of mechanical devices used to keep the bone fragments in apposition, and have finally come to use, to the exclusion of other appliances, silver plates with screws and bronze aluminum wire. Early in my experience I found that silver wire was not strong enough and often the wires broke; the fractures nearly always became displaced. I then resorted to the use of bronze aluminum wire, which has a tensile strength four times that of the silver; while the wire was strong enough a partial displacement of the fragments often occurred, no matter how the wire was applied. Then I resorted to the steel plates of Lane, and found them useful in the majority of instances, except in the case of a fractured femur or humerus, in which, if the assistant made an awkward or accidental movement while the plaster cast was applied, the screws were pulled out, and we were obliged to take off the dressing, re-open the wound and re-adjust the splint. Therefore, I now use the silver splint of Sick with four or six holes, which is flexible. It will bend rather than break or pull out and the danger of pulling out the screws, that hold the plate, is not as great as in the stiff steel plates used by Lane.

CLINICAL RESULTS OF GASTRO-ENTEROSTOMY FOR NON-MALIGNANT DISEASES*

JOHN DUDLEY DUNHAM, A.B., M.D.
Professor of Diseases of the Stomach and Dietetics, Starling-Ohio Medical College
COLUMBUS, OHIO

There have been very few accurate and thorough reports on the results of gastro-enterostomy for ulcer of the stomach.

Bettman and White[1] have collected reports of 150 cases with results after the lapse of at least one year. Bamberger[2] has studied 836 cases in which operation was performed for chronic ulcer of the stomach. The former study shows an immediate mortality of 10 per cent., the latter, 12.2 per cent. To this must be added a late mortality from complications in Bettman and White's series of 14.6 per cent. and in Bamberger's cases of 5 per cent. (complete late reports lacking in many of Bamberger's series).

We find, then a total mortality of 24.6 per cent. in one series and 17.2 per cent. in the second series. The group of 836 cases showed 74 per cent. cures; 13.4 per cent. unchanged. In the group of 150 cases there were 60 per cent. of cures and 30 per cent. of deaths, or no improvement.

The basis of the present report consists of forty-eight cases in which the patients were personally examined before operation; in all but two cases tests of the stomach contents and motility were performed. In fifteen cases examinations of stomach functions were made previous and subsequent to the operation. Forty-six patients were operated on by local surgeons, one by Dr. W. J. Mayo and one in Lausanne, Switzerland.

Fifteen patients have died, twelve within 17 days of the operation; an immediate mortality of 25 per cent.; a total mortality of 31.25 per cent; mortality since 1906, 10.41 per cent. The predominance of males (twelve males, three females), is significant. The average age is 50.5 years.

Case 8 was instructive. The patient was a man, aged 45, alcoholic, with a history of ulcer for five years with frequent severe hematemesis. Operation had been repeatedly refused. An ulcer on the anterior aspect of the stomach adjoining the pylorus was found which ruptured during manipulation. Partial gastrectomy with gastro-enterostomy was done. The patient made an uneventful recovery for fifteen days; then peritonitis developed to which he succumbed in two days. Necropsy revealed a ruptured gangrenous appendix with localized peritonitis. The site of operation was not involved. This case is an argument in favor of appendectomy with every gastro-enterostomy.

The three later deaths were due to carcinoma ventriculi in two instances, one six months, one twenty-one months after operation. In each case the patient had apparently recovered. Possibly these two ulcers had already undergone carcinomatous transformation at the time of operation. The third death resulted from recurrent hematemesis, morphinism and asthenia.

Of the fifteen fatal cases hyperchlorhydria was present in seven, anacidity in two, normal acidity in four, no determination in two. Evidence of retention of chyme was found in seven cases. Five of the patients who died had been treated medically without success. Eight patients received desultory treatment, no correct diagnosis having been made. Surgical treatment should have been given much earlier in these eight fatal cases, as shown by the advanced degree of stenosis seen at operation. Two patients (3 and 11) should not have been operated on as no stenosis was found. Recent histories have been obtained in twenty-nine of the thirty-three patients living.

Table 3 gives the data in fifteen cases in which gastric analyses were made before and at varying periods after operation. The average age at time of operation was 43.2 years. There were nine males and six females. In this group twelve had ulcer of pylorus or duodenum with stenosis; one, ulcer of pylorus without stenosis, (Case 18); another had nervous dyspepsia (Case 20) and one atony of the stomach with dilatation.

Seven patients with ulcer and stenosis made perfect recoveries, while three recovered but are obliged to abstain from acid and indigestible foods.

2. Bamberger, L.: Die innere und die chirurgische Behandlung des chronischen Magengeschwurs und ihre Erfolge, Julius Springer, Berlin, 1909

Another case (18). has improved, but has recurrent hematemesis and morphinism.

In Case 20 gastroplication was performed, leaving the patient with an aggravation of symptoms.

In Case 28 (nervous dyspepsia) the gastro-enterostomy has been followed by greater suffering than before the operation.

Examination after an Ewald test breakfast shows free hydrochloric acidity above 40 in six cases, between 20 and 40, or normal in two; below 20 in six; absent in one.

Hyperchlorhydria has increased after operation in three cases (Nos. 16, 19, 25). One of these patients (No. 16) has regained motor power and is free from

48.	1909	F.	25	Pyloric ulcer; no stenosis.	Gastro-enterostomy.	Operative Recovery.	40	60 No retention.	2

symptoms when he refrains from acid and heavy foods. The second (No. 19) has retention of chyme for ten hours, a greater hyperchlorhydria with a complete recovery from all gastric disturbances.

Hyperchlorhydria has disappeared in three cases (Nos. 21, 29, 30) and the proper motor function has been restored.

Patient 20, in spite of a clinical history of ulcer with hematemesis, had no visible ulcer scar or stenosis. Five years after operation hydrochloric acidity is within normal limits and motor power is perfect.

Patient 23, who had normal acidity, has two years after operation persistence of motor insufficiency and no improvement in condition. The six patients with hypo-acidity have suffered a variety of results. Patient 17 has developed a hyperchlorhydria, has a good motor function and is free from symptoms if he abstains from acid foods.

In Cases 18, 24 and 27 the hypo-acidity has been supplanted by an absence of free hydrochloric acid. In Case 23 the hydrochloric acid has risen to a normal degree and motor power has become established, while in Case 28 the hydrochloric acid has decreased and retention of chyme continues with the patient unimproved. Before operation Patient 26 had an absence of hydrochloric acid with marked retention of chyme. The hydrochloric acid has not reappeared, drainage is now complete within the normal time.

The appearance of bile has usually been noted one hour after the test breakfast, for four months, after which it cannot be detected. Bile was found, however, in Case 18 four years after operation.

Table 4 outlines twelve cases in which results have been ascertained from one to six years after operation. Six cases are included in which operative recoveries only are procurable (Cases 31 to 48, inclusive). In this group the diagnosis is chronic ulcer of the stomach with stenosis in fourteen; chronic ulcer without stenosis in three; nervous dyspepsia in one.

The following outline shows results in the entire series of 27 patients known to be alive.

ULCER OF STOMACH OR DUODENUM WITH STENOSIS, 21	
Perfect recovery	14
Recovery (care required as to choice of food)	4
Improved	2
Unimproved	1
	21
ULCER OF STOMACH OR DUODENUM WITHOUT STENOSIS, 3	
Perfect recovery	1
Improved	1
Unimproved	1
	3
NERVOUS DYSPEPSIA, 2	
Unimproved	2
ATONY WITH DILATATION, 1	
Unimproved	1
Total	27

A definition of the term "perfect recovery" as used in this classification depends on unqualifiedly favorable answers to the following questions:

> Do you still have trouble with your stomach? Do you have any belching of gas or food? Do you vomit at all? Have you vomited or spit up any blood since the operation? How is your appetite? Do you find it necessary to eat more than three meals a day? Are your bowels regular or do you find it necessary to take physic for them?

There must also have been the ability to pursue the former vocation or avocation without disturbance.

TABLE 3.—DATA IN 15 CASES IN WHICH GASTRIC ANALYSES WERE MADE BEFORE AND AFTER OPERATION.

Case.	Year.	Sex.	Age.	Diagnosis.	Operation.	Result.	Gastric Findings—Before Operation—HCl.	Total Acidity.		After Operation—HCl.	Total Acidity.		Date Last History.	Time Since Operation, Years.
16.	1904	F.	55	Pyloric ulcer (active); stenosis and dilatation.	Gastro-ent.	Recovery, but cannot take acid foods.	90	116	Blood.	124	152	No bile.	2/ 1/1910	6
17.	1904	M.	39	Ulcer of lesser curvature at pylorus; acute perihepatitis; adhesions of stomach to abdominal wall; stenosis.	Gastro-ent.	Recovery; recurrent attacks; hyperacidity due to errors in diet.	10	25	Retention chyme.	70	85	110 c.c.; recovered one hour after meal; no bile; no retention.	3/13/1910	6
18.	1906	F.	32	Pyloric ulcer; posterior wall; no stenosis.	Gastro-ent.	Improved; occasional hematemesis; pain; morphinism.	0	24	Blood in stool; no retention.	0	10	40 c.c. recovered; no retention; bile.	3/10/1910	4
19.	1904	M.	36	Pyloric ulcer; stenosis.	Gastro-ent.	Perfect recovery; gained 10 pounds.	50	78	Retention.	54	74	Retention after ten hours.	3/20/1910	5 1/4
20.	1905	F.	28	Neurasthenia; no ulcer or stenosis demonstrable.	Gastro-ent.	Unimproved; increase of symptoms.	30	40	No retention.	20	44	40 c.c. recovered.	3/13/1910	5
21.	1906	M.	25	Pyloric ulcer; stenosis.	Gastro-ent.	Perfect recovery; gain of 40 pounds.	60	90	Retention.	30	56	No retention.	2/14/1910	2
22.	1906	M.	60	Pyloric ulcer; stenosis.	Gastro-ent.	Perfect recovery; gain of 50 pounds.	15	35	Retention.	20	40	No retention.	3/19/1910	4
23.	1908	M.	67	Duodenal ulcer; stenosis.	Gastro-ent.	Unimproved.	25	39	Retention.	30	50	Retention.	3/13/1910	2
24.	5/ 4/1909	M.	40	Pyloric ulcer, active; stenosis.	Gastro-ent.	Recovery; must eat lightly; gain of 25 pounds.	10	16	Retention.	0	27	35 c.c. recovered; bile.	4/20/1910	11/12
25.	11/ 4/1909	M.	58	Pyloric ulcer (active); stenosis.	Gastro-ent.	Improved; gain of 10 pounds.	48	55	Retention.	50	64	Retention; bile.	5/ 1/1910	1/3
26.	10/ 4/1909	M.	30	Pyloric ulcer (ant. and post.) active; stenosis.	Gastro-ent.	Perfect recovery; gain of 30 pounds.	0	40	Retention; lactic acid.	0	20	No retention.	5/ 1/1910	7/12
27.	10/16/1909	F.	54	Pyloric ulcer; peripyloritis; stenosis.	Pylorectomy; Gastro-ent.	Perfect recovery.	2	10	Retention.	0	10	No retention; bile.	4/20/1910	5/12
28.	1/10/1910	F.	36	Atony of stomach; dilatation.	Gastro-plication.	Unimproved.	18	50	Retention.	10	30	Retention; bile.	4/10/1910	1/4
29.	3/31/1910	F.	53	Duodenal ulcer; stenosis; peripyloritis.	Gastro-ent.	Perfect recovery; gained 10 pounds.	77	85	Retention.	40	60	No retention.	5/ 4/1910	1/12
30.	1906	M.	35	Duodenal ulcer; perforation; slight stenosis.	1st repair perforation: 2nd gastro-ent.	Perfect recovery.	60	80	No retention.	38	56	No retention.	4/10/1910	4

scopically, white and red blood-cells, renal epithelia and numerous granular casts. The heart was normal, the pulse [illegible] per minute; there was increased [illegible] gastric findings in vation. 	Cases.
Hyperchlorhydria (free hydrochloric acid above 40)	19
Normal acidity (free hydrochloric acid 20-40)	14
Hypoacidity (free hydrochloric acid below 20)	7
Anacidity (free hydrochloric acid absent)	3
Total	43

This makes nineteen patients with hyperchlorhydria; twenty-four patients with normal or subnormal hydrochloric acid.

CONCLUSIONS

1. Hyperchlorhydria as a symptom of chronic gastric ulcer is inconstant and should be disregarded.
2. Perfect recovery may occur when atony of the stomach has existed before the development of ulcer and motor insufficiency persists; illustrated in Case 19.
3. Many of the fatalities cited in this report would have been averted had the family physician made a diagnosis before serious complications had developed. Forty patients in this series of cases gave a history of ulcer covering five years or more before the diagnosis was made.
4. Pylorectomy offered a better prognosis for recovery in five of the fatal cases. Patients 4, 12 and 13 were lost by fatal hemorrhages from the ulcer area. Patients 14 and 15 died as a result of carcinomatous transformation of the pyloric ulcer.
5. The legitimate field for gastro-enterostomy in benign diseases of the stomach is in chronic ulcer near or below the pylorus with stenosis.

The McLene.

ABSTRACT OF DISCUSSION

Dr. Judson Daland, Philadelphia: Chronic gastric ulcer often shows a period of latency so far as the symptoms are concerned, although the ulcer itself is still present. The patient seems to recover symptomatically. It is believed that no ulcer is present at all and the case is often pronounced cured. I recall one case in which the funicular ulcer was discovered and removed; this was followed by complete recovery. The cases of gastric ulcer referred to at another session of the Section in which the carcinoma was supposed to be cured three times belong to this same group. We see cases of chronic indolent ulcer in which under treatment great improvement results and the patients are supposed to be well.

Dr. Milton J. Lichty, Cleveland, Ohio: The study of these cases and the study of the statistics ought to be of great value and help to physicians. I should like to remind the members of the Section of the discussion of this subject three years ago by Dr. Paterson of London, when he spoke of the value of gastroenterostomy in connection with cases of gastric ulcer. He reminded us of the temporary benefit to be derived from gastroenterostomy when there was incomplete stenosis of the pylorus. I have watched cases since and must say that the best results of the gastroenterostomy were seen in cases in which the stenosis was almost absolutely complete. One does not really know just what to do with cases of incomplete stenosis of the pylorus. Of course, we cannot dictate to the surgeon just what shall be done at the time of operation, but it seems to me that in some cases in which a gastroenterostomy has been done, the patient's subsequent condition shows that it would have been better to have done a pylorectomy. It seems also that a pylorectomy should be the operation of choice whenever possible, and that a gastroenterostomy should only be done when there is complete stenosis of the pylorus.

Dr. John A. Witherspoon, Nashville, Tenn.: A few years ago a very prominent surgeon regarded this disease as a Case [illegible] The pendulum has swung back now, and every advanced surgeon is doubting the propriety of operating on gastric ulcer unless there are definite evidences of obstruction. I do not feel that gastric ulcer belongs to the surgeon for two reasons. Operation in my experience in the past has been unsuccessful. The patients I have had have recovered immediately, but later they had more or less trouble. Some of the bad ulcers become latent. It is extremely difficult in some cases to determine whether or not the gastric ulcer is cured; we know that often by medical treatment alone we may relieve patients symptomatically and they may get along well for months, gaining flesh. Yet the condition may remain dormant for some time only to awaken into activity again. A few years ago every case of hemorrhage from the stomach in cases of ulcer was referred to the surgeon for treatment; recently it has been found that medical treatment is better in such cases. The surgeon will not intervene now unless there is complete obstruction; then surgery may save many lives which otherwise would be sacrificed.

Dr. DeLancey Rochester, Buffalo, N. Y.: If there is impending obstruction, or actual obstruction, of course immediate operation is indicated. However, a gastroenterostomy is an operation that I believe should be avoided wherever possible. If any operation is to be done at all I should say that the one to be preferred was pylorectomy. I agree with Dr. Witherspoon that much can be done by medical and dietetic treatment in these cases and an operation should not be urged on patients with gastric ulcer unless it is absolutely necessary, because of the danger of cancer developing. This is a possibility, although a possibility *only*. Such good results are obtained from medical and dietetic treatment if continued for a sufficient length of time that operative measures should be avoided if possible.

Dr. A. J. Benedict, Buffalo, N. Y.: My experience with gastroenterostomy for either malignant or non-malignant disease of the pylorus is limited to one or two cases, because such an operation seemed inadvisable. In cases in which there is marked obstruction at the pylorus, a superior enterostomy is a good substitute for gastroenterostomy, the idea being to short circuit the stomach. In patients with serious lesions of the stomach the chances for betterment are increased if no food passes through this organ at all. In one patient, a woman on whom superior enterostomy was performed, a diagnosis of carcinoma was made. The patient was very much emaciated; there was pyloric obstruction and there was no free hydrochloric acid. I thought that I could feel the thickened pylorus and when the tube was passed, obstruction was also found at the cardiac end. The surgeon who was called in wanted to do gastroenterostomy, but it was decided that a superior enterostomy was to be preferred. On exposing the stomach there was found a small tumor at the pylorus. A section was not made, but taking it for granted that the tumor was a cancer, enterostomy was performed, and the patient was nourished through the fistula in the small intestines. I wish to emphasize that the diet should be watched with care. In the course of three or four weeks the symptoms in this patient were somewhat relieved; however, she had so much mental distress because of the fistula that we decided to close it, believing that she would die soon anyhow. That was in 1898. To our surprise, the woman made a good recovery and has remained well ever since. The tumor could not have been a cancer; just what it was I do not know.

Dr. Gustav Baar, Portland, Ore.: It seems to me that a mortality of 20 per cent. is too high in such cases. I have had sixteen patients operated on by surgeons during the last few years, and none died. Two of these cases were most remarkable. One patient was a woman of sixty, six feet tall, with a palpable tumor and with frequent hemorrhages; she was much emaciated, weighing but ninety-eight pounds. A gastroenterostomy was performed, and the surgeon thought that he was dealing with a carcinoma. I insisted, however, on the diagnosis of an indurated ulcer. There was free hydrochloric acid present. The patient took nourishment without the slightest distress, being given lamb chops on the third day after operation. At the end of two months her weight had increased to 168 pounds. This was only two years ago;

the patient, at this date, is perfectly well. [illegible] frequent the tumor was the size of the fist and appeared in a man *aged forty-five. He had repeated hemorrhages. A diagnosis* of indurated ulcer was made and a gastroenterostomy was performed. The man was absolutely cured. I believe that gastroenterostomy gives the most satisfactory results in all cases of pyloric ulcer and is a real boon to suffering humanity.

Dr. John D. Dunham, Columbus, Ohio: In regard to the symptomatic cure of these patients I wish to emphasize the fact that such patients should be followed for a number of years before any final conclusions regarding them should be considered. The surgeon who sees these cases finds the patients sufficiently recovered to leave the hospital and he cites such cases as recoveries. However, the general practitioner who follows the cases will often find recurrences. In the series of cases reported there was only one in which a secondary operation was called for. If the cases are properly selected and only those patients with stenosis are operated on, a secondary operation will rarely be needed. Attention to the diet is very important. These patients with partial or complete pyloric stenosis are starved, as a rule, and they require abundant feeding; they cannot live on slops; the choicest and best food properly prepared should be given them for many weeks. The food should be given frequently through the day and not as is customary, three times a day. In a consideration of the mortality the surgeon includes only the deaths which occur immediately after the operation, while the general practitioner and the internist follow the patient's history for several years. The mortality after gastroenterostomy should only be considered when the cases have been studied for five or six years. In the series I reported there were two cases in which perforation of the stomach occurred and two in which carcinoma developed.

BLOODLETTING IN CHILDREN *

HEINRICH STERN, M.D.
NEW YORK

HISTORY OF BLOODLETTING

The history of bloodletting prior to the nineteenth century gives but scant mention of the employment of this therapeutic measure in children. The very fact, however, that ancient and medieval medicine would under ordinary circumstances not dispense with depletion justifies us in assuming that the children were subjected to the same procedure, although little special reference to this custom can be found. In Stöffler's "Calendarium romanum magnum" (1518) and in the "Medicina magica" (1568) it is stated that astrology, which influenced and pervaded the entire theory and practice of medicine of the times, accepted the theory that, according to situation and conjunction of the heavenly bodies, there existed favorable, dubious and unfavorable depletion days; the various periods of life had different days on which bloodletting was to be preferentially performed.

The phase between half and full moon was deemed especially to favor depletion of young persons, but to be inimical to the operation in old people. In nurslings blood was probably never abstracted for therapeutic purposes in the olden times.

The literature of the first half of the nineteenth century contains not infrequent allusions to bloodletting in children. On the whole, the opinions of the foremost clinicians of that period were opposed to it. According to a very brief historical sketch pertaining to this epoch the amelioration of the same pathologic state as in adults. Accordingly it may be indicated in affections of theria; the latter also [illegible] organs and *diseases of the* monia and erysipelas. Bailly and the following dis- declared against the procedure in broncho[illegible]necessary (catarrhal pneumonia), but recognized its value in lobar pneumonia (fibrinous pneumonia). Among the Germans, Walther (1835), Wetzlar (1837) and Nasse (1849) expressed their opposition to blood abstraction in children. The pediatrist, Mauthner, of Vienna, on the other hand, was an energetic advocate of general and local depletion in children, especially in pneumonia and other febrile affections.

In a masterly discourse on the "Antiphlogistic Treatment in Diseases of Children," which is spread over five issues of the *Medical Record* of 1870[2] Jacobi also deals with the problem of bloodletting, and asks the question, "Are we justified in resorting to depletion at all?" He says:

> It is an established fact, or at least a very general conviction, that when we perform venesection—for the relief of pneumonia or meningitis, for example—we do not relieve the pneumonia or the meningitis itself, but we do relieve the collateral edema which has taken place in the tissues as yet uninvaded, or but partially invaded, by the inflammation. And by this relief of the collateral congestion and edema of the *meninges or of the brain, we may save a patient from approaching* dissolution. Such cases are rare; but when they occur, when we have to deal with acute edema, we must of course resort to depletion in many a case. I recall a case of convulsions in which I myself opened the jugular vein. I did not know the cause of the convulsion, but the venous congestion was so evident and so extreme, that I was led to relieve it as soon as possible. I think Trousseau relates a similar case. We know that the immediate danger in such cases depends not on the primary cause of the affection, but on the prolonged congestion, which may give rise to effusion or extravasation. To avert these I do not object to venesection—indeed, it may become imperative. . . . . But to depletion as a general antiphlogistic I must object, and this whether it be made by venesection or by local bloodletting. . . . We often hear of plethora, of surplus of blood; if such a condition ever occurs, it is certainly not in infancy. At that period any surplus would be sure to be used to build up the body, to contribute to growth.

Accordingly, Jacobi seldom resorted to depletion in inflammatory diseases of infancy and childhood, and, although meningeal and cerebral affections sometimes required direct depletion, he believes that generally, "wherever extensive derivation is really indicated," stimulation of the emunctories will be more effective than a local withdrawal of blood about the head.

The literature from 1870 to 1890 contains very little anent the subject of depletion in the young. Jewett,[3] in 1891, recommended moderate bleeding for young girls of full habit who suffer from menstrual irregularities, dysmenorrhea or temporary suspension of the flow, accompanied by flushed face, headache and a throbbing pulse. Lisner,[4] in 1897, published the following interesting case:

> A boy, 8 years old, well developed, was affected with a mild form of scarlatina. The disease had about abated when a grave nephritis supervened. The eyelids were edematous; the urine contained about 1 per cent. albumin and showed, micro-

scopically, white and red blood-cells, renal epithelia and numerous granular casts. The heart was normal, the pulse 96 per minute; there was increased tension; no temperature elevation. The usual therapeutic measures were ineffective. Urinary examination, performed daily, showed no decrease of albumin; the general condition, which was fair at the onset, became worse. Without somnolence or other distinct premonitory symptoms uremia supervened suddenly, with four rapidly succeeding convulsive attacks, one of which lasted about half an hour and affected particularly the right half of the body. Chloroform inhalations caused momentary relief but did not prevent repetition of the convulsive attacks, which ensued with greater frequency and intensity. The child was apparently moribund. As the pulse was still strong, however, venesection was resorted to, though very little hope was held out for recovery. About 100 c.c. blood were withdrawn from the right median cephalic vein. The result was more striking than any the observer had ever noticed following therapeutic intervention. Movements of the right arm were perceived even while the blood was still flowing. Three additional but very mild convulsive attacks ensued after depletion; the patient slept during the night. The subsequent course of the affection was also surprising; the urinary albumin decreased slowly but steadily; ten days later albumin was no longer found in the urine; the edema of the eyelids disappeared and the improvement in the general condition was rapid.

Marfan,[5] in 1897, dwelling on therapeutic considerations concerning the diseases of childhood, remarks that general depletion should not be employed before the fourth or fifth year of life, because abstraction of body liquids below this age is not well borne. He maintains, on the other hand, that local depletion by means of leeches or wet cupping, which often yielded excellent results, may already be applied after the fifteenth month of life. Concerning the action of topical depletion he has to say the following:

> Ces émissions agissent d'une manière complexe, à la fois par la soustraction d'une petite quantité de sang et par la révulsion, qui est très vive avec la ventouse scarifiée, très spéciale avec la sangsue.

At the onset of lobar pneumonia he applies one or two wet cups beneath the nipple of the affected side; in meningeal states and grave convulsions, one or two leeches behind the mastoid processes, or two or three wet cups on the nape of the neck will sometimes appease the untoward phenomena; and in cases of nephritis with anuria or uremia, he concludes, the application of from two to four leeches or wet cups on the lumbar region often constitutes a heroic treatment.

Murray[6] in the same year published a note of caution concerning bloodletting in children. He says that when children are bled to faintness the recovery is slow and even convulsions and death may ensue.

The most important communications on the question before us were made by Baginsky[1] in 1898 and 1901, respectively. In his first article he gives the histories of three of his cases:

CASE 1.—Girl, aged 7½, affected with grave pneumonia and arrhythmia; facial pallor, cyanosis of the lips, extreme dyspnea; orthopneic posture; pulse not palpable; diffuse rhonchi; enlargement of liver; albuminuria with numerous anatomic elements. The increasing dyspnea, threatening the life of the child, the great restlessness and fear, prompted withdrawal of 120 c.c. blood. This was very dark. Even while the process of depletion was still going on the intense cyanosis became relieved, the lips red, the pulse palpable, respiration slower. Sleep ensued. Recovery.

CASE 2.—Boy, aged 9, affected with pulmonary cirrhosis, bronchiectasis and asthmatic attacks. Improvement ensued after abstraction of from 80 to 100 c.c. blood.

CASE 3.—Girl, aged 7. In June, 1897, she was treated in the hospital for pneumonia. Since then the child was ailing. Seriously sick for the previous few days, she was again admitted to the hospital Dec. 19, 1897. Patient was suffering extreme dyspnea and was nearly dead of exhaustion; respiration involved exertion of all respiratory muscles and strong movements of larynx and thorax; wings of the nostrils far apart and moved with respiration; cyanosis of lips; pulse not palpable; dull sound in place of cardiac sounds; loud bronchial râles. Injection of camphor and mustard bath produced no improvement; venesection resorted to; median vein of right arm first, that of left arm subsequently, were incised. But a few drops of blood escaped from either vein. The child was apparently moribund, and section of the radial artery seemed justifiable. About 80 c.c. arterial blood was withdrawn. The blood was very dark. Cyanosis disappeared quickly, the pulse became palpable, dyspnea was relieved and the general condition became encouraging. The child stated that it felt better. Thoracic phenomena persisted for some time. A livid, morbilliform eruption had been present. The further course was undisturbed. The phenomena of a grave, diffuse bronchitis abated gradually; otitis media was intercurrent; the exanthema followed its normal course; the child was discharged as cured July 7, 1898.

On the strength of his clinical experience Baginsky maintains that venesection (or, if necessary, arteriotomy) must be frankly conceded to be a life-saving procedure, even in younger children, in the presence of an engorged right heart and consequent circulatory difficulty. The fact that blood abstraction may prevent a fatal issue he ascribes to its purely mechanical effect; depletion relieves the engorged and incompetent heart and reestablishes the passage of the blood through heart and lungs; however, it is not effective in every instance in which it is indicated, as the cardiac muscle may be too far deteriorated to again functionate properly.

A brief article by Gregor of the Pediatric Clinic of Breslau University, published in 1900,[7] deals with bloodletting in nurslings. He states that many physicians not rarely apply leeches in children under 1 year of age in the treatment of pneumonia or when there is suspicion of intracranial congestion. At the Breslau clinic venesection has been performed on nurslings between the fourth and eighth months of life when there existed extensive pulmonary disease. Depletion in these cases was, however, undertaken at a stage of the malady when, as a consequence of blood-pressure decline, thrombosis of the opened vein ensued rapidly and the abstraction of sufficient amounts of blood was no longer possible. However, in a 6-months-old nursling with bilateral pneumonia and imminent cardiac insufficiency, venesection was successfully applied; the child was brought through the exudative stage until, by the occurrence of a vicarious emphysema, the danger of respiratory insufficiency had been averted. Gregor is prompted by the happy issue of this case to employ venesection in nurslings affected with pneumonia (in cases in which one lung becomes rapidly involved after the other and digitalis proves ineffectual to regulate cardiac activity) at a time before the blood-pressure has markedly decreased.

In an article devoted to venesection in uremia consequental to scarlatinal nephritis, Singer,[8] in 1905, champions the therapeutic measure. He has observed nineteen cases of uremia in the course of scarlet fever. In all venesection was made use of. Fifteen patients recovered, four died. In eight instances the improvement was immediate; the convulsions ceased and consciousness reappeared at once. In children with a small, frequent pulse blood abstraction was followed by better results than when a pulse of different quality obtained. A filiform pulse contraindicates venesection. The operation, Singer maintains, is particularly called for when cerebral irritation governs the picture of the disease. When a comatose state prevails the chance for recovery is not so favorable.

As I am not a pediatrist, my personal clinical experience with general depletion in children is naturally limited and dates back to my days of general practice, shortly after the time of the first article of Baginsky on the subject. I have performed venesection eight times in children, viz., in two cases of bronchopneumonia, one case of lobar pneumonia and five cases of uremia. In the cases of bronchopneumonia and lobar pneumonia resort to bloodletting was had too late in the course of the disease, and all the children died. Of the five children with uremic manifestations, three survived. Concerning one of the latter cases I gather from the brief notes in my possession the following:

A girl, aged 7, exhibited the symptoms of postscarlatinal nephritis in the fourth, and those of uremia in the fifth week after the onset of the original affection. There were the usual nervous and urinary phenomena, the various edematous conditions, high vascular tension, dilated heart and subnormal temperature. To prevent edema of the lungs, which seemed imminent, blood was abstracted from the most prominent vein in each arm. Together about 60 c.c. were withdrawn. The high tension subsided rapidly, the temperature (rectal) became elevated to 100 F. within one hour, and the child was overcome with a natural sleep which lasted a few hours. After another week the child was out of danger; the swelling subsided, the urine had cleared up to a remarkable degree, and there were no undue cardiac or vascular manifestations. There was an uninterrupted recovery.

INDICATIONS AND CONTRAINDICATIONS

The opinion prevails among most of those who have contributed to the subject since the revival of bloodletting in the beginning of the nineties of the last century that early age, *per se,* offers no specific contraindication to the employment of this therapeutic procedure. In principle all these clinicians advocate bloodletting in suitable cases, although Marfan[5] does not wish to see general depletion used in children under 4 years and topical depletion in those under 15 months of life. On the other hand, the physicians of the Breslau Pediatric Clinic do not hesitate to take recourse to venesection in the nursling when it seems indicated (Gregor[7]). Singer[6] maintains that venesection is a potent and appropriate remedy in uremia arising in the course of scarlatinal nephritis, and he applies it in all types of children—the strong, the weak and the anemic; the only contraindication to bloodletting he recognizes is the presence of a filiform pulse. It goes without saying that general depletion is a much more energetic measure in children than in adults, principally for the reason that hematosis is rather an uncertain and tedious process in early life, and it must not be forgotten that the infant needs every drop of its blood at the moment the acute condition demanding depletion has subsided.

The authors cited in the foregoing have obtained beneficial results from bloodletting, especially in instances of pneumonia and of nephritis with uremic manifestations. These are also the principal affections for the treatment of which depletion has been employed in adults. Moreover, there seem to exist no special reasons why depletion in children should not be undertaken for the amelioration of the same pathologic state as in adults. Accordingly it may be indicated in affections of the heart and circulatory organs and diseases of the nervous system. Baginsky[1] recounts the following diseases in which blood abstraction may become necessary in children: pleuropneumonia, bronchopneumonia, capillary bronchitis with hyperemic manifestations, chronic heart disease, rapidly succeeding convulsions caused by hyperemia of the brain, and grave nephritides with uremic symptoms.

The action of full depletion in all these diseases is probably a mere mechanical one. In that group of affections in which orthopnea and dyspnea, regardless of their origin, dominate the acute clinical picture, the removal of adequate amounts of blood suddenly relieves the right heart, which, from the accumulation therein of venous blood, has become engorged, dilated and incompetent. In those clinical pictures in which coma or convulsive states overshadow the other manifestations bloodletting diminishes the underlying hyperemia of the brain, the irritation of the cerebral cortex and the vasoconstriction very likely in an entirely mechanical manner. Apart from the fact that a hemocathartic or detoxicating influence of bloodletting has never been fully demonstrated, the suddenness of the relief afforded in uremia stamps depletion as a mechanical or physical therapeutic agent.

In both groups of syndromes danger is imminent; on the one hand impending suffocation; on the other, coma or convulsions, while pulmonary edema is threatening in either case. In all pertaining instances in which the child is apparently moribund, bloodletting is unreservedly indicated.

We know at the present day that depletion does not produce a general antiphlogistic or antipyretic effect; general bloodletting neither reduces the body temperature nor subdues inflammation. Our grandfathers in medicine considered nearly every disease to be of an inflammatory character, for which vigorous antiphlogistic treatment had to be instituted. Their antiphlogistic therapy consisted for the most part in bloodletting. Jacobi[2] has given the death-blow to the practice of general antiphlogosis by depletion in children. In the treatment of the general run of acute diseases in children and infants blood abstraction is contraindicated unless the phenomena of suffocation, pulmonary edema, coma or convulsions, demanding mechanical relief, are paramount. On the other hand, topical bloodletting may exert a local antiphlogistic effect, as Marfan[5] and others assert, for the pediatric practice. Experimental proof of this clinical observation is not lacking. Nicholas[9] has shown, in the web of curarized frogs, that clinging of leukocytes to the vessel wall and their transmigration, retardation of the blood-current and, finally, stasis are manifestations of inflammation, while the opposite phenomena follow local blood abstraction, and consist of acceleration of the circulation, cessation of transmigration of leukocytes, their detachment from the vessel wall and resumption of their movements and activity in the increased blood current.

Bloodletting in children is distinctly contraindicated in instances of chronic hydremia and the cachectic states.

AMOUNT OF BLOOD TO BE WITHDRAWN IN CHILDREN

In local depletion the amount of blood withdrawn is always small. It is generally gauged by the number of leeches which have been applied. Marfan,[5] as already

---

9. Nicolas: Ueber locale Blutentziehungen als antiphlogistische Operationen nebst einschlägigen Experimenten, 1882.

mentioned, has given some practical hints as regards topical bleeding in a number of affections.

General depletion will prove of little or no avail if insufficient amounts of blood are abstracted. Yet, in children, the blood frequently ceases to flow before a sufficient quantity has been obtained. Under these circumstances it is often justifiable to resort to arteriotomy. The egress of the blood is livelier in the afternoon or evening than in the morning. Cold enhances coagulation and, hence, causes cessation of the blood flow. Baginsky[1] declares that if the blood escapes normally and without interruption the fifteenth or twentieth part of the entire blood of the child may be withdrawn with impunity. According to the same author if the entire blood of the child amounts to from one-fifteenth to one-twentieth of his body-weight, the quantities of blood shown in the accompanying table may be abstracted:

TABLE SHOWING AMOUNT OF BLOOD THAT MAY BE SAFELY ABSTRACTED AT DIFFERENT AGES, ETC.

Years of Life.	Body Weight in Kilograms.	Total amount of Blood. in Kilograms.	Amount to be Withdrawn.
One	10	0.66–0.5	45– 25 c.c.
Three	12.5	0.85–0.62	65– 45 c.c.
Five	16	1.1 –0.8	73– 50 c.c.
Seven	20	1.3 –1.	85– 50 c.c.
Ten	24.5	1.65–1.23	110– 85 c.c.
Fourteen	38.5	2.57–1.92	170–100 c.c.

These are merely approximate amounts; occasionally more blood may be withdrawn, especially in cases of uremia. In other instances a smaller depletion may be safer for the child and still be sufficient to accomplish the desired end. Singer[8] mentions, relative to scarlatinal nephritis, that the amount of blood to be removed should be in proportion to the age of the patient and the severity of the attack. If bloodletting does not yield satisfactory results, so that neither the syndrome or the patient's general condition change materially, depletion may be repeated in from twelve to twenty-four hours.

METHODS AND TECHNIC OF GENERAL DEPLETION IN CHILDREN

General depletion may be accomplished by either arteriotomy, venesection or venepuncture. Arteriotomy should be resorted to in cases of existing or imminent pulmonary edema. It should be undertaken only by one who has sufficient surgical experience. In the great majority of cases, however, the blood is withdrawn from a vein. Prior to the era of aseptic surgery phlebotomy was effected by means of a spring-lancet; in modern times the little operation is performed with the scalpel. One of the veins of the arm may be incised; the median, the median cephalic or median basilic vein are best suited for the purpose. In other instances the blood may be obtained from one of the saphenous veins in the leg. In children, especially in infants, the veins of the arms are little prominent and are more or less hidden by goodly layers of adipose tissue. Baginsky recommends the free dissection of the vein and a long incision into it. Venepuncture, whenever applicable, is that method of blood abstraction which should be given preference. On account of the little prominence of the arm veins and the comparatively extensive fatty bolster in the young subject, it is probably not possible to employ it as frequently in children as in adults. The little blood, on the other hand, which it is often possible to obtain from one vein only should prove no contraindication to the employment of venepuncture; the little puncture wound is of no account and the instrument may be inserted into a number of veins until the desired amount of blood has been secured. The advantages of venepuncture over venesection are: greater simplicity, greater safety for both patient and physician, greater cleanliness, more rapid accomplishment of the purpose, possibility of immediate intravenous saline infusion after abstraction, rapid healing of the small puncture wound. I have devised a venepuncture trocar, the description of which has already been published.[10]

The instrument is employed as follows: After the arm is corded as for venesection the thumb-rest of the trocar is held between thumb and index-finger, while the middle finger rests against the handle of the perforator to prevent it from sliding backward. The operator then thrusts the trocar directly into the most prominent vein of the forearm—the right, if possible. The puncture is made so that the point of the trocar is toward the axilla, and, although the needle points in the same direction as the blood-current, the blood flows out readily when the perforator is withdrawn beyond the outlet. A piece of rubber tubing should be attached to the outlet before the instrument is introduced into the vein. To the free end of the tubing a glass connecting tube should be fastened. The tubing and glass tube should lead into a graduated vessel, so that the operator may ascertain the amount of blood withdrawn. Immediately after depletion, when the cannula is still in position, an infusion may be administered through the same tubing and outlet. All that there is to do to accomplish this purpose is to connect the glass tube with the tubing of the vessel containing the saline solution, and to remove the material used for constricting the arm. The chance of injuring nerves and arteries is reduced to a minimum by inserting the trocar into the cephalic vein, which is not situated in as close proximity to these structures as is the median basilic, which is the vein most frequently chosen for venesection in the adult. The chance of admitting air into the vein when employing the trocar is entirely eliminated.

In the adult, bloodletting by venepuncture is one of the simplest operations imaginable. It is readily executed by any physician and I have as yet to hear the first objection to its employment by the patient or his relatives. In the child and infant the operation is a little more difficult on account of the slight prominence of the veins and the fat tissue of the arms; here the walls of the veins are not as tough as in the adult life, and great care must be exercised that the trocar needles the vein and does not penetrate it on the other side.

In concluding I wish to say that bloodletting in proper cases is probably the most potent single remedial measure which we possess, and if I again have drawn the attention of the pediatrist to this subject, it is to awaken interest in the clinical study of this old remedy through modern eyes and with modern methods of observation.

250 West Seventy-third Street.

ABSTRACT OF DISCUSSION

Dr. E. Mather Sill, New York: I can imagine that bloodletting would be very good to diminish the blood-pressure in cases of edema due to congestion. I have been accustomed to use aconite and sweating in these cases rather than bloodletting. I find that in cases of congestion due to bronchopneumonia, the old-fashioned method of cupping gives relief. Bloodletting would be contra-indicated in pneumonia, in which the children are "run down." In cases of pneumonia in children, especially babies, the patients are much affected by loss of blood and if this bloodletting is performed it seems to me that a saline infusion should always be used to take its place. I am of the opinion that it would be very important to have a standard whereby we could know just how much blood to let in certain cases according to the age and condition of the child. I should say that it would be indicated only if the child was robust and strong and contra-indicated in cases of anemia and malnutrition.

---

[10] Med. Rec., New York, Dec. 23, 1905.

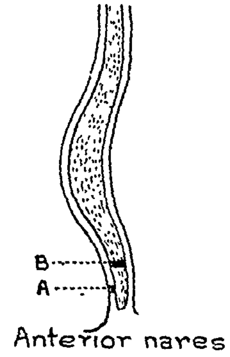
Dr. Abraham Jacobi, New York: I can only repeat what I said forty years ago (*New York Med. Record* of 1870), and forty years ago I spoke on an experience of seventeen years in practice in New York. I have not modified my opinion expressed at that time. We must not forget that we cannot say beforehand uniformly just how much blood should be taken. The patients and the cases are not alike. We should remember that the amount of blood is present in a different percentage in the adult. The baby has about 5 per cent. of its weight in blood (1 part blood in 19½ body weight) while the adult has nearly 8 per cent. (1 part blood in 13 body weight). If a child weighs 40 pounds, about 2 pounds only would be the amount of blood in that child and in that proportion only the blood should be taken. No large percentage of the amount circulating in the body should be taken away.

Dr. Heinrich Stern, New York: Dr. Jacobi has again hit the nail on its head. The amount of blood to be abstracted in the young should always be in proportion to the amount contained in the organism, and we know that the blood ratio in children is decidedly smaller than in the adult. It should never exceed in the general run of cases 50 to 100 c.c.

AN ORIGINAL METHOD FOR PREVENTION OF PERFORATION IN SUBMUCOUS RESECTION

RICHARD M. NELSON, M.D.
Eye, Ear, Nose and Throat Clinic, Colon Hospital
CRISTOBAL, CANAL ZONE

In every adverse criticism of the operation of submucous resection for the correction of deviation or deflection of the nasal septum which I have read or have heard, the greatest stress has always been laid on the danger of perforation resulting therefrom. Indeed, such great emphasis is laid on this danger, that in every such operation which I have performed the dread of this occurrence has ever been foremost in my mind.



Diagrammatic horizontal section through a septum deflected to the right. A, initial incision through mucous membrane down to cartilage. (Usual method is to cut through cartilage also here.) B, incision through cartilage only, a quarter or an eighth of an inch posterior to incision in mucous membrane. Both incisions, of course, are made from the right.

Believing that it ought to be possible to devise some modification of the usual steps of this operation rendering the danger of perforation less than was to be apprehended with existing methods, I set to work to put into practical use an idea that had often suggested itself to me in operating after the usual method. I noted on several occasions that in dissecting or separating the mucous membrane from the cartilage on both sides, although I several times made "buttonholes" in the mucous membranes of both sides in a single operation, I never had a perforation result.

In looking for an explanation for this I noted that in no case had any two "buttonholes" been made opposite one another. The idea naturally suggested itself to apply this principle in making the initial incisions. In the next operation, after making the first incision through the mucous membrane, etc., down to the cartilage, and separating the membrane from it as far back as necessary, instead of cutting through the cartilage at the same line of incision followed in going through the membrane, the cartilage was carefully cut through from one-eighth to one-fourth inch posterior to the incision through the mucous membrane. The rest of the operation was done after the usual methods. At the close of the operation, instead of the cartilage being cut off flush with the incision through the mucous membrane, there was left a projecting ledge of cartilage extending from one-eighth to one-quarter of an inch posteriorly from the line of this incision. In bringing the raw surfaces of mucous membrane together this projecting ledge of cartilage was found not only to be completely covered over, but also to appear to aid very materially in holding the edges of the wound in close apposition, acting somewhat as a natural splint.

I have tried this method in a series of cases with uniform results, without a perforation, and I would state that in my opinion with ordinary care and reasonable exercise of even moderate skill it is practically impossible to produce a perforation in using this method of making the primary incisions.

A PRACTICAL MECHANICAL METHOD OF END-TO-END ANASTOMOSIS OF BLOOD-VESSELS

USING ABSORBABLE MAGNESIUM RINGS

V. D. LESPINASSE, M.D., G. CARL FISHER, M.D., and
J. EISENSTAEDT, M.D., D.D.S.
CHICAGO

This work was done in the laboratory of the department of Experimental Surgery of Northwestern University Medical School, with the cooperation and assistance of Prof. Robert Zeit and Drs. Wolfer, Violet Deason and Solmon. It is accomplished by the use of rings of metallic magnesium.

PHYSICAL PROPERTIES AND METALLURGY OF MAGNESIUM

Magnesium is a hard, silver-white metal, having a specific gravity of 1.75 and possessing a melting point of 800 degrees. As it tarnishes in the air the bright luster is soon lost, but the change is unimportant at the ordinary temperature. At a high temperature combustion follows, with production of the well-known brilliant white light. At ordinary room temperature the action increases and hydrogen gas is slowly liberated, the hydroxid of magnesium being formed at the same time.

The action of water on magnesium is hastened by the presence of salts, such as sodium chlorid, from which it follows that in the juices of the body the solution or disappearance of the metal would be more rapid than in water alone. However, even with salts present, the action is relatively slow and the hydrogen set free is scarcely appreciable. Under proper conditions 24 milligrams of magnesium will liberate 2 milligrams of hydrogen, or 22.4 c.c. at the normal temperature of zero centigrade. This volume would be somewhat greater at body temperature; approximately, 1 mg. of the metal will liberate 1 cubic centimeter of the gas.

A 3.5 mm. ring, such as would be used on a dog's carotid, produces about 60 c.c. of gas. A 9 mm. ring, such as would be used on a human femoral, produces about 240 c.c. of gas. This gas is produced slowly and is absorbed almost as fast as produced; hence it does no harm.

Several different explanations of the action of magnesium with salt solution have been given but for all practical purposes the formation of magnesium hydroxid and hydrogen may be considered as covering the main features of the changes. The products formed are non-toxic and non-irritant.

The metal is very brittle and breaks suddenly when it is bent at a right angle, but it is quite resistant to a pull or crush.

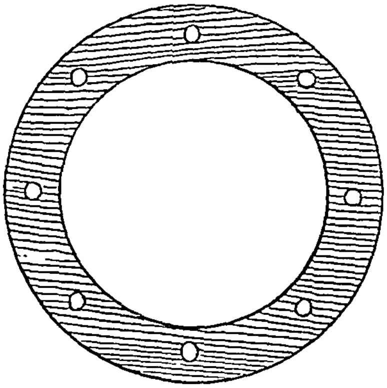


Fig. 1.—A ring, a flat piece of metallic magnesium, with edges rounded off and eight holes punched in it equidistant. These holes are counter sunk so that their edges will not cut the threads.

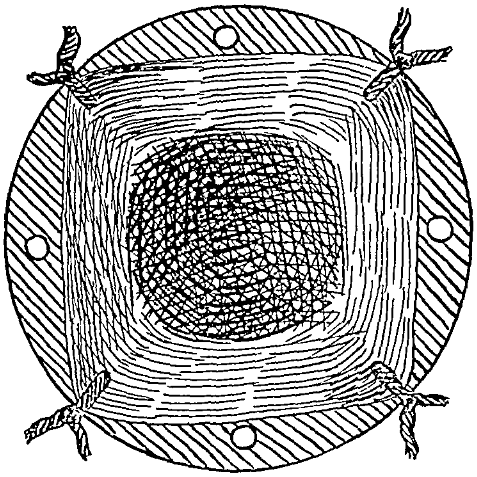

Fig. 2.—Vessel sewed into the ring, using every other hole; the sutures are triple O silk.

STERILIZATION

The rings are boiled in water from Lake Michigan, which does not contain much salt. Where the water contains any considerable amount of salts, one should use distilled water.

METHODS

Many methods of blood-vessel anastomosis have been advanced but they are all lacking in some way. The only methods at all practicable at the present time are first, the Payr method, second, the suture method.

The Payr method constricts the lumen of the vessel and is very liable to secondary thrombosis, while the technic of the suture method is very difficult. In the method here advanced these objections are overcome. There is no constriction, secondary thrombosis is impossible and the technic is simplicity itself. In a properly applied union there is not one drop of hemorrhage. One is master of the situation at all times, and does not have to try slight pressure, hot sponges, and other temporizing and uncertain methods, to stop the oozing of the blood after the clamps are removed. He knows that when the clamps are removed his junction will be perfect; if anything is wrong, *it will be easily detected during the operation and can* be remedied at once. While a suture may look ever so well, it may still bleed furiously when the clamps are removed, showing that the approximation is imperfect and the whole operation is destroyed beyond repair. Secondary attempts at repair have in my experience been failures in every instance.

TECHNIC OF MAGNESIUM RING BLOOD-VESSEL ANASTOMOSIS

The first step in the operation is the dissection and exposure of the vessel. This must be done carefully, and all collaterals must be clamped, cut and ligated. Then the loose sheath and adventitia is dissected off as completely as possible. As the blood flows through the vessel, the diameter of the vessel is accurately determined by the use of a millimeter gauge, which is a very important step in the operation, as the vessels, surgically speaking, have very little elasticity in a transverse direction; the fact is this elasticity is just sufficient to maintain the original lumen of the vessel, and allow for the everted portion necessary to make the anastomosis. The diameter of the vessel determined, a ring should be used having a lumen of the same diameter as that of the blood-vessel, while the blood is flowing through the vessel. If the vessel has been clamped and cut before it is measured the measurement should be taken proximal to the proximal clamp. Next the vessel is clamped in two places by means of the ordinary Crile clamp. These clamps are tightened just sufficiently to shut off the blood-stream, but not tightly enough to traumatize the intima; the vessel is then cut midway between the two clamps. The distance between the two clamps before cutting should be an inch and a half to two inches; this allows a sufficient working distance on each cut end of the vessel. The anastomosis can be done with much less space than this if necessary, but with a corresponding increase in the difficulties of the technic. After the vessel is cut the ends retract widely The cut ends draw themselves down into and are covered over by a portion of the sheath and adventitia; grasp this connective tissue with tissue forceps; draw it up, and cut it off flush with the cut end of each vessel. The adventitia then slips well back, and is entirely out of the way for the remainder of the operation. Each end of the blood-vessel is then washed out with a normal saline solution discharged from a large syringe. In the smaller vessels, it is best to grasp them just distal to the clamp with a Knapp trachoma roller, and thus the clotted blood is forced out of them. During this process of rolling, a stream of saline solution should be playing on the cut end of the vessel.

The vessel is now ready for the application of the rings. These rings may be used in the following ways: First, one ring and a lock-stitch; second, two rings which are sewed into the respective ends of the vessel; third, two rings and four ligatures; fourth, two rings, one of which is threaded.

First Method: One ring and lock stitch.

An appropriate-sized ring is slipped over one end of the vessel; then four guy ligatures, equidistant, are passed through the ends of the vessel; next the lock stitch is passed, first through the vessel walls, and then through the rings. The loops of the stitch are cut, and the appropriate ends tied together. The lock stitch consists of eight needles; or if the ring has more than eight holes, then have the same number of needles as there are holes in the ring. These needles are all threaded on a single thread, being spaced about eight inches apart. The two ends of the thread are passed through the same needle. In this method the ring acts only as a splint, to prevent constriction of the vessel, and every portion of the vessel wall is in the grasp of the suture; hence there is practically no hemorrhage.

Second Method: Two rings are used which are sewed into the respective ends of the vessel, by four sutures of triple-0 silk, using every other hole (Fig. 2).

In tying these sutures, care should be taken that the knot is on the outer edge of the ring, or on the opposite side of the ring from the intima of the vessel. After the rings have been sewed into the ends of both vessels, the two rings are united by four stitches passing first through one ring, then through the blood-vessel, then through the blood vessel on the opposite side, and finally through the opposite ring. These four sutures are then tied over the edge of the rings. This method is a poor one, first, because there is a liability of the suture cutting through the metal of the ring; second, it only provides four points of pressure on the ring and hemorrhage is liable to occur; third, it gives a chance for spreading of the rings at their inner edge with exposure of the sutures and consequent thrombosis.

The sutures joining the rings together had better be placed as a mattress stitch, which is done in the following way (Fig. 3):

Four strands of fine silk or linen about eight inches long are selected and armed with a needle on each end. These sutures should be perfectly smooth and withstand at least an 8-lb. pull. One of the needles is passed through the same hole in the ring through which a fine silk suture has been passed; the other end of the suture is passed through an adjoining hole in the ring, and then through the blood-vessel wall. On the other ring the sutures are passed through the same relative holes. Four of these mattress sutures are passed. After the sutures are all in place, they are pulled together and approximate the rings accurately, with no tendency for the rings to spread, and there is no liability of the sutures cutting through the large amount of metal in their grasp (Fig. 4).

Third Method: Two rings and four guy ligatures.

An appropriate-sized ring is slipped over each end of the vessel. Two ends of the vessel are then united together by four guy ligatures placed equidistant from each other. A suture is then passed through the ring, through the two ends of the vessel, immediately beneath the guy ligatures; then through a hole in the opposite ring. The suture is passed back through an adjoining hole in the second ring, through the two ends of the blood-vessel, midway between the guy ligatures and finally through the adjoining hole of the first ring. Three other sutures are passed and then the four sutures are drawn up and tied. The guy ligatures are cut and the operation is completed.

Fourth Method: Two rings, one of which is threaded.

Four strands of fine linen are armed on each end with a needle. These strands are threaded through an appropriate-sized ring in such a manner as to make four mattress stitches, having all the loops on the same side of the ring; this ring is then slipped over the cut end of the vessel; the vessel is grasped at points exactly opposite, by two very fine tenaculums; the needle directly opposite the first needle inserted is now passed through the blood-vessel, exactly between the tenaculums but on the opposite side; the remaining needles are now passed in their appropriate places. The first two needles are indicated by being grasped in marked mosquito forceps. The opposite cut end of the vessel is now grasped by two fine tenaculums at points directly opposite each other. The two marked sutures are now passed through the vessel, midway between the tenaculums and on their appropriate sides; then they are passed through their appropriate holes in the second ring; the remaining sutures are then passed in their proper places through the vessel and through their proper holes in the second ring. The tenaculums are removed and the sutures drawn up and tied.

For large vessels, namely, above 5 mm. in diameter, the fourth method is preferred; for smaller vessels, the best method is the second here mentioned, passing the sutures uniting the rings as a mattress stitch. All sutures are heavily smeared with petroleum. These sutures need not be boiled in petroleum. The petroleum is put on first to strengthen the thread and second to make it slip easily through the tissues and not drag connective tissue with the thread into the lumen of the vessel. And the petroleum is not intended, as in the suture method, to prevent thrombosis.

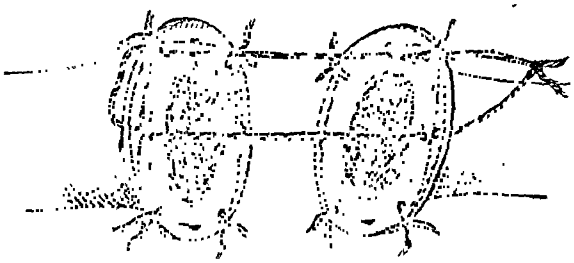

Fig. 3.—The two rings and one of the four approximating sutures of linen passed. Three others are passed in exactly the same way.

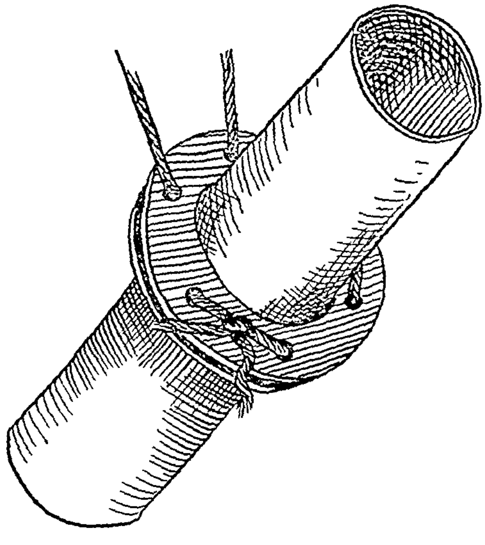

Fig. 4.—The two rings drawn together and three of the approximating sutures tied while the fourth one is drawn up ready to be tied.

After the sutures are pulled up and tied, the clamps are removed, removing the distal one first. The fascia of the sheath is then sewed over the line of union, and the operation is completed.

THE METHOD FOR REPAIR OF A LONGITUDINAL SLIT IN A BLOOD-VESSEL

In this operation the ring is replaced by a thin plate of metallic magnesium 1.5 mm. wide with holes 3 mm. apart (Fig. 6).

Technic: Clamp the vessel above and below the slit. Then locate the ends of the slit. Pass a guy ligature through the vessel walls at each end of the slit; select two plates a trifle longer than the slit; pass the needle, first through the end hole in one plate, then through both walls of the vessel a trifle beyond the end of the slit; next through the first hole in the opposite plate, then back through the second hole of the second plate, through the vessel walls on both sides of the slit; about 1 mm. from the edge, and finally through the second hole of the first plate. Taking another suture it is passed through the third and fourth holes of the plates in exactly the same way, and so on, the number of sutures depending on the length of the slit (Fig. 7).

ABSORBABILITY

The period within which the magnesium rings are absorbed varies from 80 to 100 days for complete absorption. They maintain their original shape and hold for about thirty days and then begin to break down.

TYING THE SUTURES

It has been determined that a ligature passed around a large artery and tied under five pounds pressure will shut off the blood stream but not injure the intima. A ligature passed in the same way but tied under eight pounds' pressure will cut the intima. Hence to bind the two rings together the sutures should be tied with a pressure of more than five and less than eight pounds. Throughout the operation the ends of the vessel should be washed in saline solution every few minutes. Occasionally, if the vessel is not thoroughly cleaned of connective tissue and the sutures are passed from without inward, a small tag of connective tissue may catch in the suture and be dragged through the vessel wall and project into the lumen. One point that must be carefully watched in regard to the sutures which hold the rings together is their cleanliness. These sutures must not be permitted to come in contact with blood or serum. This can be avoided by the use of gauze sponges or a piece of dentist's rubber dam appropriately placed. If the sutures are not kept clean the material adherent to them is stripped off by the blood-vessel walls as the sutures are drawn up and collects as little masses around the sutures and form the starting points for thrombi.

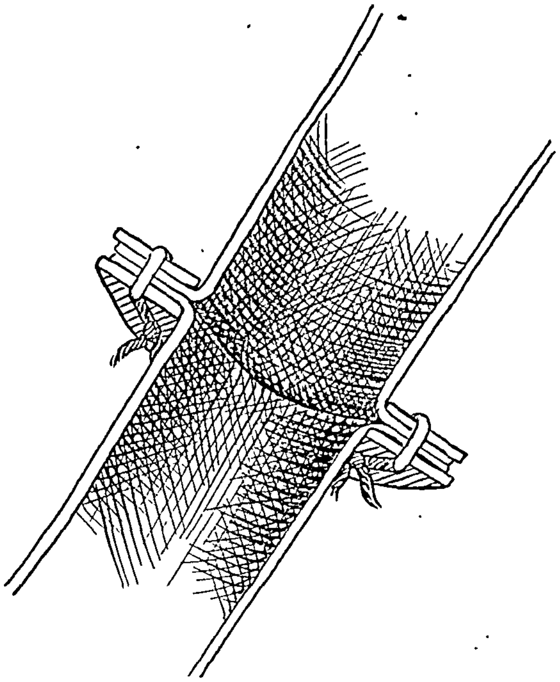

Fig. 5.—A longitudinal section of the vessel. It also shows that no foreign material of any kind comes in contact with the blood after the operation is completed.

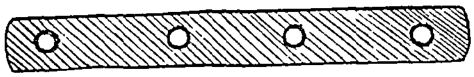

Fig. 6.—A magnesium plate suitable for repair of a lateral slit in a vessel.

THROMBOSIS

In this method there is nothing inside of the lumen of the vessels after the operation is completed; hence if trauma to the intima is avoided during the operation and the vessel is washed free from all clots and not tied tightly enough so that the rings will cut the intima where it bends outward to form the flange, thrombosis will not occur. Secondary thrombosis, such as occurs in the Payr operation from pressure necrosis, is impossible.

STRICTURE

In this method primary stricture cannot occur if the vessel is accurately measured and an appropriate-sized ring is at hand with which to make the anastomosis. Secondary stricture has never occurred in any of my experimental operations. In one specimen there was a small pouch at the site of operation.

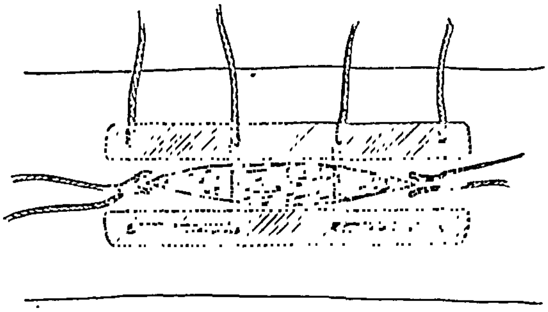

Fig. 7.—A lateral slit with a guy rope passed through each end of the slit and two mattress sutures passed through the two plates and the vessel wall ready to be drawn up and tied.

HEMORRHAGE

Primary hemorrhage should not occur. In most of the anastomoses, there is absolutely no hemorrhage, not even a drop; secondary hemorrhage has occurred only in the presence of infection.

EMBOLUS

There is danger of this occurring only when thrombosis is present; hence to avoid embolus, avoid thrombosis. Its seriousness depends entirely on the point of lodgment of the embolus.

SUMMARY

The following principles must be kept in mind when making blood-vessel anastomoses with magnesium rings:

1. The vessel must be accurately and cleanly dissected.
2. *All wound hemorrhage and oozing must be checked.*
3. All clot must be removed from the ends of the blood-vessel.
4. A proper-sized ring must be used.
5. The rings must not be tied together under more than 8-lb. pressure or less than 5 lbs.
6. Traumatism to the intima behind the line of union must be avoided absolutely.

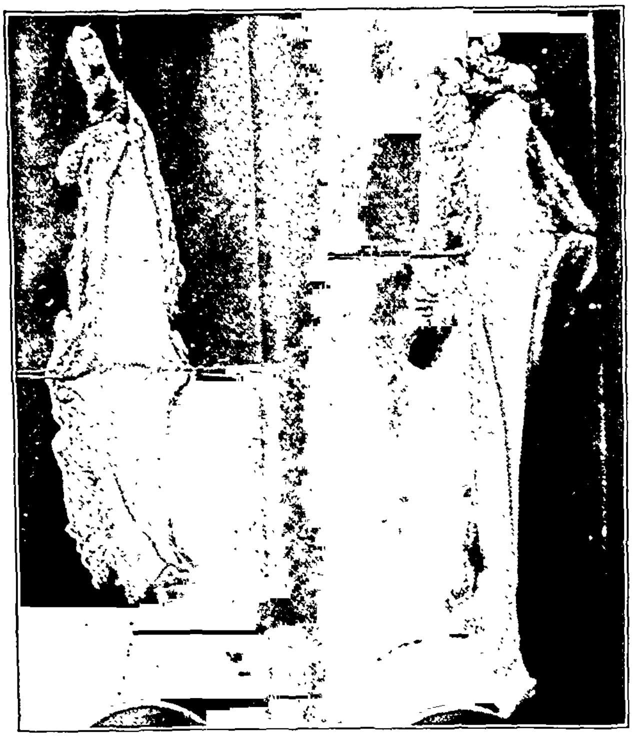

Fig. 8.—Result of anastomosis of common carotids after 100 days No clots, no thrombosis, no constriction; arteries were pulsating and spurted when cut; magnesium rings absorbed.

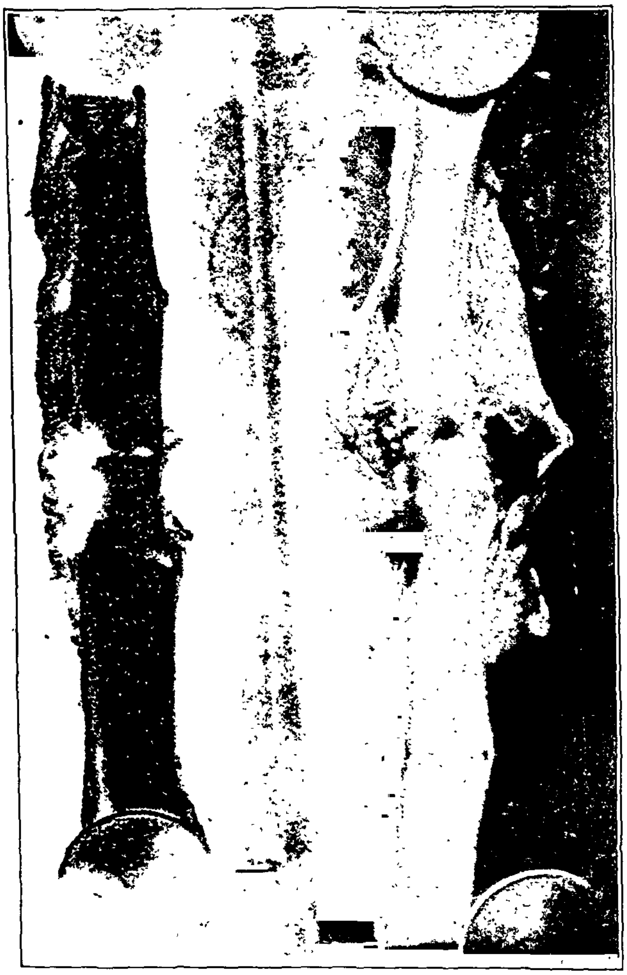

Fig. 9.—Result of common carotid operation. Dog died 36 days after operation; cause unknown. One vessel shows large gas tumor; neither showed any clot or thrombosis.

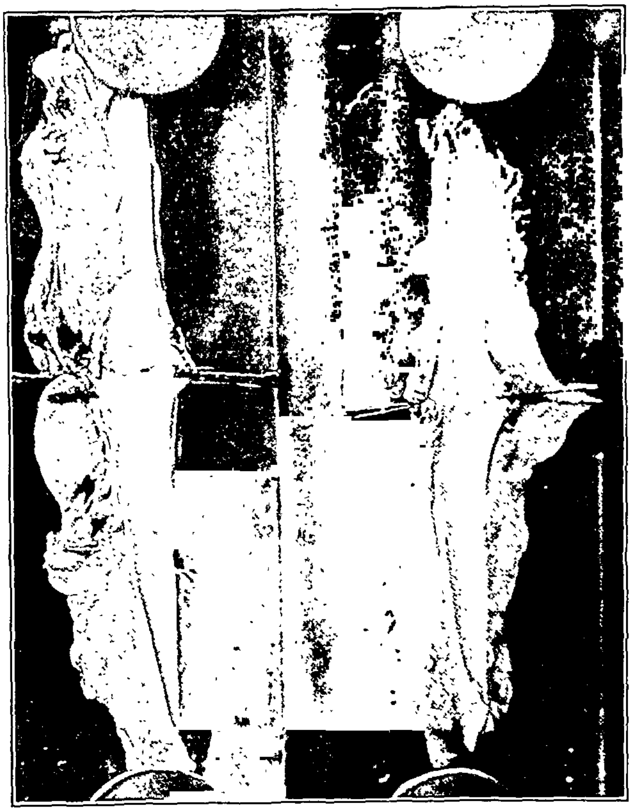

Fig. 10.—Common carotid operation. Dog killed 112 days later. The arteries were dissected out and demonstrated to be pulsating. They were clamped and cut distal to the anastomosis. In each instance the blood spurted. The vessels were then split open and mounted. *Age of operation 112 days; magnesium practically gone;* few small pieces still present; vessel smooth; no constriction.

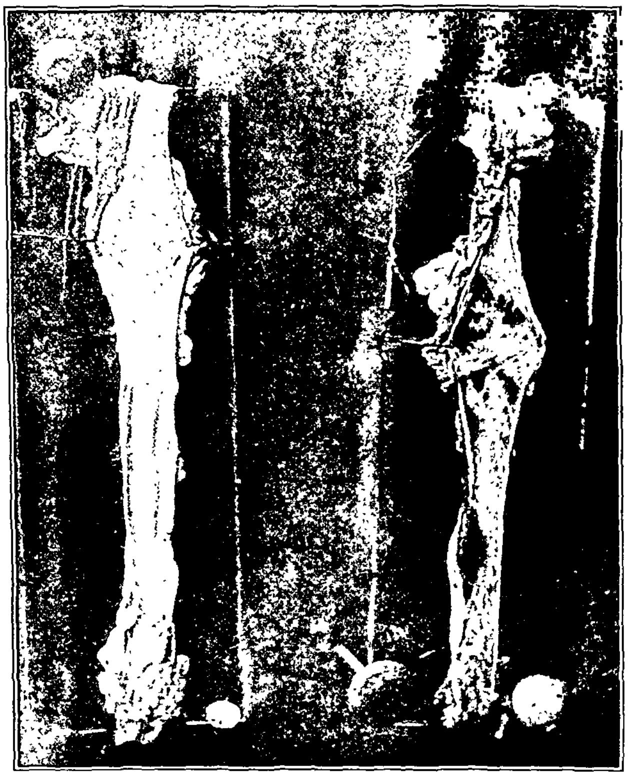

Fig. 11.—End-to-end anastomosis of external jugular vein. Operation 84 days old. Vessels smooth on the outside; blood flowing through them; magnesium rings absorbed except two small pieces in the tissue; no gas present. On opening the vessel; intima smooth and site of anastomosis determined with difficulty; 4 mm. rings used

7. Gentleness and accuracy in all manipulations is absolutely essential.
8. Perfect asepsis must be maintained.

CONCLUSIONS

The use of magnesium rings to anastomose blood-vessels makes the operation safe, certain and easy, bringing it well within the skill of the average surgeon.

At the present time this operation is applicable, and should be done, in all wounds of the large vessels, both venous and arterial, and in all false aneurisms; and in all arterio-venous aneurisms. Under these conditions the short piece of vessel containing the opening can be removed bringing the ends together and making an end-to-end anastomosis, thus reestablishing the circulation through the vessel.

72 Madison Street.

ABSENCE OF HYDROCHLORIC ACID WITH BLOOD IN THE STOMACH SECRETION (ACHLORHYDRIA HEMORRHAGICA GASTRICA) AS A SYMPTOM OF CHRONIC GASTRITIS *

JAMES TAFT PILCHER, M.D.
BROOKLYN

The purpose of the present communication is to describe a condition which has been encountered many times among the cases of stomach disease which have presented for treatment at St. Mary's Hospital of Rochester, Minn., during one and a half years, all of whom have been personally examined by me. In making these examinations some 4,000 stomach extracts after an Ewald test meal have been analyzed. Of this entire number I can recall only seven to which the term "achylia gastrica" might be applied, and there was but one case of real insufficiency of the pylorus, which was determined at operation. On the other hand, the absence of free hydrochloric acid, accompanied by occult blood, was observed in 271 instances, or approximately one in every *fifteen stomachs examined.*

In various instances every gradation between normal acidity and achlorhydria has been observed, and in yet other cases it has been possible to watch the gradual return from a condition of achlorhydria hemorrhagica back to regained normal acidity.

The anamnesis developed the fact that in 156 of the 271 cases of achlorhydria the onset of the gastric symptoms seemed to bear an immediate and direct relation to various *diseases and conditions, among which the* incidence of infectious diseases in thirty-eight cases, circulatory disturbances in twelve, postoperative development in fourteen, and derangement of the ductless glands in twenty instances deserve mention. In contradistinction to these etiologic factors determined clinically, it is very significant that in 100 cases an operation was performed while a condition of achlorhydria hemorrhagica gastrica was present. The gross pathologic findings in these showed involvement of the appendix in thirty-six cases, the gall-bladder in thirty-two cases, the gall-bladder and pancreas sixteen cases, the stomach sixteen cases. There were twelve cases in which the appendix was diseased concomitantly with the gall-bladder.

Appreciating generally the extraordinary degree of gastric disturbance which irritation in distant organs can produce, it may be considered even more than a presumptive conclusion that reflex nervous phenomena are responsible primarily for the inhibition of the production of hydrochloric acid in such instances.

The morbid anatomy of the stomach and pylorus in these patients is also of interest. Sixty-four were apparently normal. In twenty-four pylorospasm was demonstrated on the operating table, accompanying appendicitis eighteen times, and gall-bladder involvement six times. There were four cases in which Dr. Mayo deemed it advisable to cut off former gastro-enterostomies done elsewhere, there being no pathologic indication for their continuance. In two cases ulcer of the stomach was found, in one pyloric insufficiency, in three the pylorus was *markedly thickened; there was one* congenital stenosis, and one hour-glass contraction.

Regarding the pathology of the stomach mucosa in cases which do not show any free hydrochloric acid, it would be well to consider the study made by Drs. Wilson and MacCarty of 230 stomachs resected by Dr. Mayo for carcinoma.[1] In the majority of these hydrochloric acid was absent, yet in none of them was a general atrophy of the mucous membrane found. On the other hand, there was present almost without exception a marked proliferation of the mucous membrane at the margin of the ulcer. There is, however, usually an accompanying round-cell infiltration of the submucosa of a greater or less degree.

In considering the similar derangement of the gastric secretion in cases in which no carcinoma is present, I have obtained specimens from three stomachs exhibiting this phenomenon. The most noticeable findings are the occurrence in each of unquestionable non-contiguous erosions or ulcerations of the mucosa (Fig. 1), in places down to the muscularis, and a very evident submucosal infiltration of round cells (Fig. 2). Further, in many situations there was a marked engorgement of the capillaries, apparently due to the inflammatory reaction. Lying irregularly over the epithelium were masses of yellowish blood pigment, which are not found in normal stomachs, as was shown by many controls, and I feel justified in suggesting that they are probably due to a precipitation of the ferruginous element contained in the serum, which, it is evident from analogy, must exude from the eroded and inflamed areas.

The explanation of the entire *modus operandi* may be found in considering the following facts, which seem to have been fairly well established, and their correlation demonstrated:

First, a primary inhibition of the hydrochloric acid (reflexly produced); second, an invasion of the stomach by pathogenic organisms, especially streptococci, causing irritation of the mucosa; and third, a superficial ulcerated erosion of the mucosa.

Calling to mind evidence tending to prove the above, we have to consider:

First, inferentially:

1. Food causes pain, the acids being the worst.
2. Relief by vomiting, lavage and alkalies.
3. Restoration of hydrochloric acid after operation and treatment.
4. Disappearance of blood from test meal after treatment.
5. Complete disappearance of gastric symptoms after removal of irritant (appendix, gall-stones, etc.).
6. Various progressive and retrogressive phases as indicated previously.

---

* Read before the American Gastro-Enterological Association, St. Louis, June 6, 1910.

* From the Pathologic Laboratories of St. Mary's Hospital, Rochester, Minn.

[1] Am. Jour. Med., 1909, cxxxviii, 846.

Second, objectively:

1. Absolute evidences of strong reflexes (pylorospasm).
2. Presence of micro-organisms (streptococcus, diplococcus, colon).
3. Absence of same in cases of normal acidity.
4. Normal gross appearance of these stomachs.
5. No thickening, cicatrices or atrophy when palpated.

Third, pathologically:

Macroscopic and microscopic demonstration of erosions of mucosa and round-cell infiltration of submucosa.

BACTERIOLOGY

In 350 specimens from 150 of these stomachs, stained at various intervals of time, the following organisms were found present with the indicated frequency:

Streptococci	127 cases	Diplococci (marked)	84 cases
Colon alone	8 cases	Lactic acid bacilli	42 cases
Streptococci and colon	64 cases		

Staphylococcus, proteus and leptothrix were always present. In several instances the cells of the mucosa itself had taken on phagocytic properties. Degenerated leukocytes were almost always present; in quantities large enough to be designated as pus in forty-eight cases. These findings have been amply controlled by repeated observations of the flora existing in cases of hyperacidity, normal, and hypo-acidity, and in malignant and non-malignant stenoses, with the result that the following conclusions seemed to be indicated:

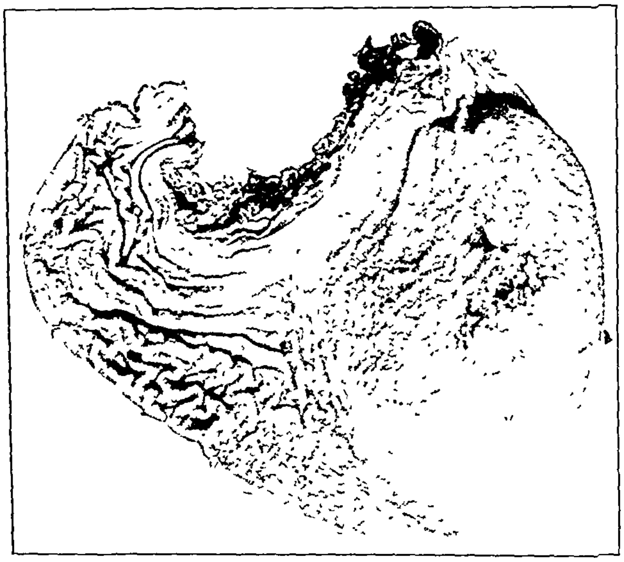

Fig. 1.—Gross appearance of posterior wall of stomach showing non-contiguous erosions or superficial ulcerations in fundus.

In the stomachs of patients presenting the symptom of achlorhydria hemorrhagica there is present a very large number of bacteria. Varieties ordinarily pathogenic are almost universally found, either alone or in combination.

Their presence is dependent on the lowered acidity of the gastric juice.

They are actively growing bacteria, evidenced by their profusion, morphologic characteristics and staining properties.

The streptococci are probably the most important factors, since they are found in larger numbers in those cases in which pus has been noted.

This would seem to be proof of some active irritation which would also account for the inferred presence of erosions of the mucosa.

The erosions of the mucosa are further indicated by the pain complained of.

The yellow color in the extracts and the blood reaction must both apparently be due to the oozing or seeping of serum from these erosions.

The sour, bitter, acrid eructations are the result of the formation of organic gases.

DIAGNOSIS

The determination of the presence of this symptom can, of course, only be made with accuracy by an analysis of the stomach contents, and this is quite characteristic either when considered grossly, chemically, or microscopically.

The amount recovered is usually less than that ingested. The bread is in a very coarse state of division, and practically as it has been swallowed. There is a uniform absence of viscosity, but the bread is quite frequently incorporated in thin mucus.

The color varies from a yellow tinge, just off the white, to a light orange. There is occasionally a slightly rancid odor.

The filtrate is invariably crystal clear and may have a slight yellowish tinge.

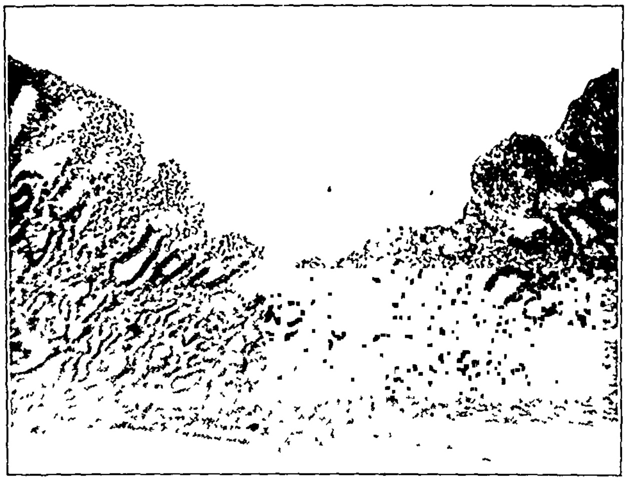

Fig 2.—From photomicrograph through defect in mucosa shown in Figure 1, showing destruction of epithelium and round-cell infiltration of submucosa.

The total acidity varies between 6 and 8 points, and is due to the acidity of the ingested bread. Free hydrochloric acid is never present. Combined acids are practically negative. Traces have, however, occasionally been found.

Lactic acid is present in about 15 per cent. of the cases, but the Strauss method must be used, as by Uffelman's method a perfect reaction is nearly always obtained, due to the lack of masking by hydrochloric acid.

The blood reaction is always present, the guaiac test in a modified form being employed. It is always of the so-called "occult" variety, and never traumatic. If it were, the extract would be red, and it would not be an admixture or diffuse. This reaction has been amply controlled in order to convince myself that the title proposed in this paper was justified.

Remnants are seldom found, and if obtained are due to continuous pylorospasm.

I have found the biuret reaction present in a much greater percentage than other observers have found it.

SYMPTOMATOLOGY

The symptom-complex in this class of cases presenting the symptom of achlorhydria hemorrhagica gastrica is rather difficult to define, chiefly because of the inconstancy of the accompanying symptoms, and yet it is on this very capriciousness that the chief point in diagnosis must be based.

The majority of these patients complain of oppression or distress in the epigastrium, amounting usually to a sensation of pain. In most cases it is of a burning or gnawing character, and occurred in one-third of the cases immediately after food. This does not always obtain, as they will say at times it occurs much later, or even before meals. The expression "at any time" is a familiar one, until the patients are required to state the inception more definitely. It is usually increased by taking food, although it may be relieved, temporarily. Various methods for its more permanent relief are to be noted, vomiting being the most prominent. Belching and sour, bitter, acrid eructations are a constant accompaniment.

In at least one-half of the cases vomiting is complained of, usually immediately after meals, consisting of the ingesta, which have a sour, bitter taste. Nausea is not infrequent, and hematemesis has occurred in several instances. Constipation is usual, but this may alternate with periods—usually of one to four weeks—of diarrhea, while in one class of cases the imperativeness of bowel movement immediately after eating is very suggestive of this derangement.

There is usually discrimination used by these patients as to the quality and quantity of food eaten, meats and fats being the first to be discarded. Very marked impairment of the appetite is present in many instances, although here also vagaries are to be noted. The loss of weight, averaging between 15 and 25 pounds, is an almost constant finding.

Generally patients with achlorhydria present a perverted mental attitude, and have periods of depression alternating with nervous excitement. All these factors I am inclined to think are rather the result of the condition due to the continued thought exercised by many of the so-called dyspeptics concerning their stomachs, or the fear induced by the idea of cancer being present, rather than a causative factor of the condition itself, which seems to be explicable on a much sounder pathologic basis than that of a neurosis. Malaise, easy fatigue, inability to work, occasional headaches, and insomnia, complete in a general way the symptomatology presented by the majority of the cases in this series.

Among the conditions which must be differentiated are gastric and duodenal ulcer, cancer and cardiospasm, also pregnancy, uremia, phthisis, urokinetic conditions, chronic obstructions of the colon, diseases of the nervous system, tabetic crises, hysterical vomiting, angina pectoris, abdominal angina and muco-membranous colitis. The relative value of each I hope to demonstrate in a subsequent article.

The coexistence of the etiologic factors (cholecystitis, appendicitis, pancreatitis, etc.) with their more or less obvious symptomatology, must be taken into consideration primarily.

TREATMENT

Treatment resolves itself into either medical or surgical. The latter is certainly indicated when any pathologic condition can be determined on. In view of our inability to diagnose any etiologic factor, the best results have been obtained from proper regulation of the diet and from the employment of the alkalies in combination with general tonics.

In the cases considered, 172 patients have been traced and their personal statement of their present condition tabulated. Sixty-one patients have entirely recovered, thirty-eight have merely an occasional complaint, twenty-three feel comparatively well, nine are moderately improved. In twenty-six there was no improvement, while four were worse, and eleven had died.

The greatest improvement has been obtained in those operated on. Of the eleven recorded as dead, we find the primary factor, as pancreatitis, nephritis, myocarditis, pernicious anemia, etc., given usually as the cause. One I know developed a cancer in the stomach, and two gave a history very suggestive of it, but it could not be confirmed.

SUMMARY

There is a definite entity presented in the stomachs of some patients suffering from various intra-abdominal and extra-abdominal pathologic conditions, which is characterized by the absence of hydrochloric acid and the presence of "occult" blood.

This condition is probably effected through the agency of a reflex nerve stimulation inhibiting first the production of free hydrochloric acid to only a moderate degree.

This so modifies the inhibiting factor of the gastric juice that the necessary conditions for the growth of pathogenic bacteria are furnished, chief among which are to be reckoned the streptococci and colon group, which are present in striking numbers.

These direct irritants, either themselves or in conjunction with a primary irritative factor, *e. g.*, gallstones, appendicitis, pancreatitis, etc., perpetuate the pathologic process until there is an achlorhydria produced. It is most probable that to the ulcerative erosion following this irritation the presence of blood may be ascribed.

In the 100 stomachs examined at operation atrophy was never present, nor was there, except in one case, any evident insufficiency of the pylorus.

There is a general symptomatology accompanying this condition which is very suggestive.

The test meal recovered is indicative of the pathologic process in the stomach.

There were indications in but seven cases observed that there was no secretion from the stomach mucosa. In others the presence of mucus, the biuret reaction and coagulation after activation would tend to show that there was still a moderate degree of enzymatic action. The cases are therefore not "achylia gastrica."

Proof of the etiologic factors has been deduced from the prompt and permanent recovery of the patients operated on.

The condition is so common, approximately one in every fifteen stomach cases in which the patients were examined, and the indication it gives of irritation in other organs I believe is so firmly established, not to mention the potential factor for future trouble which it itself contains, that it merits more frequent consideration in the study of possible gastric conditions.

I wish to take this occasion to express my appreciation of the kindness of Dr. W. J. Mayo in placing at my disposal this clinical and surgical material, which has made these investigations possible; and also my indebtedness to Dr. L. B. Wilson for many valuable suggestions in the course of this research.

THE PLACE OF HEBOSTEOTOMY AS AN AID TO DELIVERY *

CHANNING W. BARRETT, M.D.

Professor of Gynecology Medical Department of the University of Illinois and Chicago Policlinic School; Gynecologist to Chicago Policlinic School and Hospital; Gynecologist to Henrotin Memorial Hospital; Obstetrician to Cook County Hospital

CHICAGO

Since pregnancy in woman usually consists in single fetation and since the child is born needing the care of the mother for years to come, that obstetric treatment *which does not strive to the utmost to result in a living* healthy mother and child ignores the fundamental purpose of pregnancy, namely, reproduction.

The obstetric art cannot afford to be wasteful of a single life. As long as there is a child mortality of 2 per cent., as reported by Hill, as well as a maternal mortality and morbidity and due directly or indirectly to disproportion between the size of the passage and the passenger, we are entirely justified in our efforts to secure for each mother and child that treatment best adapted to their needs.

APPLICATION AND LIMITATION OF HEBOSTEOTOMY

Hebosteotomy must be considered in the light of its success in certain conditions in which other measures fail and its limitations must be set only by the greater success of other procedures to terminate the pregnancy safely for mother and child, to which end the state and the individual has a right to expect that every means possible be brought to bear. Two important erroneous impressions obtain in this relation: first, that pregnancy and labor are physiologic processes and second, that when they cease to be so, the separation of the mother and child at all hazards to the child constitute successful obstetrics. When we consider the number of maternal and fetal deaths, the invalidism in mothers from tears, infections, hemorrhages, etc., and the crippled and mentally defective children that result, it will be seen that it were greater wisdom to consider them pathologic processes. This would send the obstetrician to his case better equipped mentally as well as materially. This would also do away with the midwife, one of the greatest inconsistences of modern medicine. As to the second point, it may not always be possible to save mother and child but failure to do so allows the pregnancy to fail of its purpose and this should not be until every measure at our command is exhausted. Good obstetrics means not only watchful expectancy for a spontaneous delivery but wise intervention looking toward the saving of the life and health of mother and child.

Not every practitioner has acquired such skill in pelvic measurements that he can determine the amount of contraction, flattening, narrowing of the pelvic arch, exostoses, size of the child's head, etc., to a nicety; neither can an expert estimate the proportions to a certainty, but such skill can be acquired as will foretell a probable difficult labor and too much emphasis cannot be laid on the importance of seeking hospital care and the services of one skilled in obstetric technic in order that the right step may be taken at the right time.

METHODS OF DELIVERY

The purpose of this paper is to review some of the methods in use in the presence of disproportion between the child's head and the pelvis of the mother and to deal in particular with one of these methods—hebosteotomy.

1. A marked degree of contraction has been considered a justifiable excuse for abortion in the early months of pregnancy, but if we do not presume to judge between human lives 100 per cent. fetal mortality is too high a price to pay.
2. Artificial labor is sometimes induced after the period of viability has been reached in moderate degrees of contraction.
3. Efforts have been made, and with reported success, to control the growth of the child during the latter months of pregnancy.
4. Labor is allowed to continue beyond the usual length of time in order that a disproportionally large head may mold.
5. The high forceps are applied and efforts made to drag the head into and through the pelvis.
6. Version is performed to force delivery of the mother at the expense of the child.

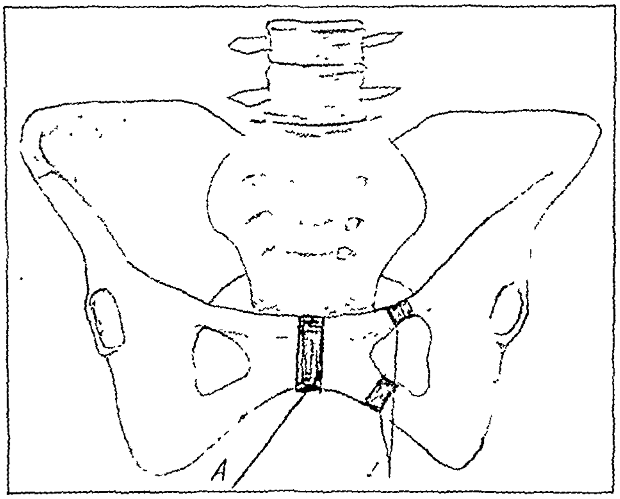

Fig 1.—Diagram of (A) Sigault's symphyseotomy (1777) and (B) Pinard's ischiopubiotomy (1892).

7. Craniotomy is performed even in the living child by some.
8. Cesarean section is chosen when a medium or marked degree of contraction is known to exist or when it is discovered while the child is still living, head not engaged, and the mother still in fair condition and uninfected. In some instances these objections might be set aside in favor of Cesarean section.
9. Enlargement of the pelvis to meet the disproportion is accomplished by separating the symphysis, or preferably cutting through the body of the pubic bone, the first known as symphyseotomy and the latter variously known as pubiotomy, hebotomy, etc., but preferably called hebosteotomy.

I would not wish to say that any one of these methods is without its field of usefulness in some hands, but I should have to have a stronger indication for abortion and craniotomy than that a patient did not wish to submit to a fairly safe obstetric operation. The periods of pregnancy and labor are no times for a woman to prove a "quitter." I should say that she has no right to ask the life of the child that she may avoid hebosteotomy or a comparatively safe Cesarean section.

It is usually increased by taking food, although it may be relieved, temporarily. Various methods for its more permanent relief are to be noted, vomiting being the most prominent. Belching and sour, bitter, acrid eructations are a constant accompaniment.

In at least one-half of the cases vomiting is complained of, usually immediately after meals, consisting of the ingesta, which have a sour, bitter taste. Nausea is not infrequent, and hematemesis has occurred in several instances. Constipation is usual, but this may alternate with periods—usually of one to four weeks—of diarrhea, while in one class of cases the imperativeness of bowel movement immediately after eating is very suggestive of this derangement.

There is usually discrimination used by these patients as to the quality and quantity of food eaten, meats and fats being the first to be discarded. Very marked impairment of the appetite is present in many instances, although here also vagaries are to be noted. The loss of weight, averaging between 15 and 25 pounds, is an almost constant finding.

Generally patients with achlorhydria present a perverted mental attitude, and have periods of depression alternating with nervous excitement. All these factors I am inclined to think are rather the result of the condition due to the continued thought exercised by many of the so-called dyspeptics concerning their stomachs, or the fear induced by the idea of cancer being present, rather than a causative factor of the condition itself, which seems to be explicable on a much sounder pathologic basis than that of a neurosis. Malaise, easy fatigue, inability to work, occasional headaches, and insomnia, complete in a general way the symptomatology presented by the majority of the cases in this series.

Among the conditions which must be differentiated are gastric and duodenal ulcer, cancer and cardiospasm, also pregnancy, uremia, phthisis, urokinetic conditions, chronic obstructions of the colon, diseases of the nervous system, tabetic crises, hysterical vomiting, angina pectoris, abdominal angina and muco-membranous colitis. The relative value of each I hope to demonstrate in a subsequent article.

The coexistence of the etiologic factors (cholecystitis, appendicitis, pancreatitis, etc.) with their more or less obvious symptomatology, must be taken into consideration primarily.

TREATMENT

Treatment resolves itself into either medical or surgical. The latter is certainly indicated when any pathologic condition can be determined on. In view of our inability to diagnose any etiologic factor, the best results have been obtained from proper regulation of the diet and from the employment of the alkalies in combination with general tonics.

In the cases considered, 172 patients have been traced and their personal statement of their present condition tabulated. Sixty-one patients have entirely recovered, thirty-eight have merely an occasional complaint, twenty-three feel comparatively well, nine are moderately improved. In twenty-six there was no improvement, while four were worse, and eleven had died.

The greatest improvement has been obtained in those operated on. Of the eleven recorded as dead, we find the primary factor, as pancreatitis, nephritis, myocarditis, pernicious anemia, etc., given usually as the cause. One I know developed a cancer in the stomach, and two gave a history very suggestive of it, but it could not be confirmed.

SUMMARY

There is a definite entity presented in the stomachs of some patients suffering from various intra-abdominal and extra-abdominal pathologic conditions, which is characterized by the absence of hydrochloric acid and the presence of "occult" blood.

This condition is probably effected through the agency of a reflex nerve stimulation inhibiting first the production of free hydrochloric acid to only a moderate degree.

This so modifies the inhibiting factor of the gastric juice that the necessary conditions for the growth of pathogenic bacteria are furnished, chief among which are to be reckoned the streptococci and colon group, which are present in striking numbers.

These direct irritants, either themselves or in conjunction with a primary irritative factor, *e. g.*, gallstones, appendicitis, pancreatitis, etc., perpetuate the pathologic process until there is an achlorhydria produced. It is most probable that to the ulcerative erosion following this irritation the presence of blood may be ascribed.

In the 100 stomachs examined at operation atrophy was never present, nor was there, except in one case, any evident insufficiency of the pylorus.

There is a general symptomatology accompanying this condition which is very suggestive.

The test meal recovered is indicative of the pathologic process in the stomach.

There were indications in but seven cases observed that there was no secretion from the stomach mucosa. In others the presence of mucus, the biuret reaction and coagulation after activation would tend to show that there was still a moderate degree of enzymatic action. The cases are therefore not "achylia gastrica."

Proof of the etiologic factors has been deduced from the prompt and permanent recovery of the patients operated on.

The condition is so common, approximately one in every fifteen stomach cases in which the patients were examined, and the indication it gives of irritation in other organs I believe is so firmly established, not to mention the potential factor for future trouble which it itself contains, that it merits more frequent consideration in the study of possible gastric conditions.

I wish to take this occasion to express my appreciation of the kindness of Dr. W. J. Mayo in placing at my disposal this clinical and surgical material, which has made these investigations possible, and also my indebtedness to Dr. L. B. Wilson for many valuable suggestions in the course of this research.

THE PLACE OF HEBOSTEOTOMY AS AN AID TO DELIVERY *

CHANNING W. BARRETT, M.D.
Professor of Gynecology Medical Department of the University of Illinois and Chicago Policlinic School; Gynecologist to Chicago Policlinic School and Hospital; Gynecologist to Henrotin Memorial Hospital; Obstetrician to Cook County Hospital
CHICAGO

Since pregnancy in woman usually consists in single fetation and since the child is born needing the care of the mother for years to come, that obstetric treatment which does not strive to the utmost to result in a living healthy mother and child ignores the fundamental purpose of pregnancy, namely, reproduction.

The obstetric art cannot afford to be wasteful of a single life. As long as there is a child mortality of 2 per cent., as reported by Hill, as well as a maternal mortality and morbidity and due directly or indirectly to disproportion between the size of the passage and the passenger, we are entirely justified in our efforts to secure for each mother and child that treatment best adapted to their needs.

APPLICATION AND LIMITATION OF HEBOSTEOTOMY

Hebosteotomy must be considered in the light of its success in certain conditions in which other measures fail and its limitations must be set only by the greater success of other procedures to terminate the pregnancy safely for mother and child, to which end the state and the individual has a right to expect that every means possible be brought to bear. Two important erroneous impressions obtain in this relation: first, that pregnancy and labor are physiologic processes and second, that when they cease to be so, the separation of the mother and child at all hazards to the child constitute successful obstetrics. When we consider the number of maternal and fetal deaths, the invalidism in mothers from tears, infections, hemorrhages, etc., and the crippled and mentally defective children that result, it will be seen that it were greater wisdom to consider them pathologic processes. This would send the obstetrician to his case better equipped mentally as well as materially. This would also do away with the midwife, one of the greatest inconsistences of modern medicine. As to the second point, it may not always be possible to save mother and child but failure to do so allows the pregnancy to fail of its purpose and this should not be until every measure at our command is exhausted. Good obstetrics means not only watchful expectancy for a spontaneous delivery but wise intervention looking toward the saving of the life and health of mother and child.

Not every practitioner has acquired such skill in pelvic measurements that he can determine the amount of contraction, flattening, narrowing of the pelvic arch, exostoses, size of the child's head, etc., to a nicety; neither can an expert estimate the proportions to a certainty, but such skill can be acquired as will foretell a probable difficult labor and too much emphasis cannot be laid on the importance of seeking hospital care and the services of one skilled in obstetric technic in order that the right step may be taken at the right time.

METHODS OF DELIVERY

The purpose of this paper is to review some of the methods in use in the presence of disproportion between the child's head and the pelvis of the mother and to deal in particular with one of these methods—*hebosteotomy*.

1. A marked degree of contraction has been considered a justifiable excuse for abortion in the early months of pregnancy, but if we do not presume to judge between human lives 100 per cent. fetal mortality is too high a price to pay.
2. Artificial labor is sometimes induced after the period of viability has been reached in moderate degrees of contraction.
3. Efforts have been made, and with reported success, to control the growth of the child during the latter months of pregnancy.
4. Labor is allowed to continue beyond the usual length of time in order that a disproportionally large head may mold.
5. The high forceps are applied and efforts made to drag the head into and through the pelvis.
6. Version is performed to force delivery of the mother at the expense of the child.

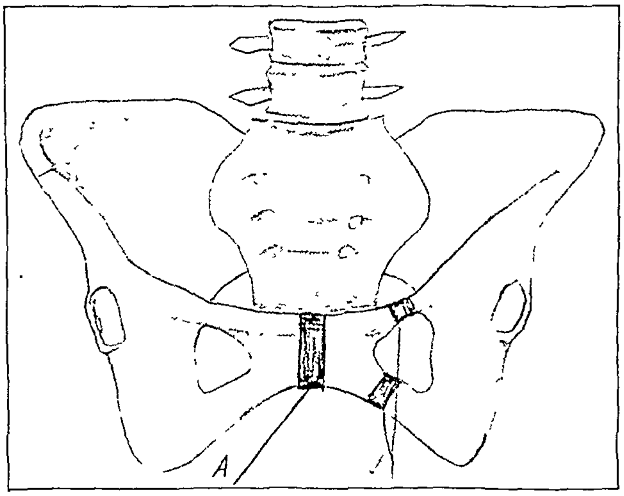

Fig 1.—Diagram of (A) Sigault's symphyseotomy (1777) and (B) Pinard's ischiopubiotomy (1892).

7. Craniotomy is performed even in the living child by some.
8. Cesarean section is chosen when a medium or marked degree of contraction is known to exist or when it is discovered while the child is still living, head not engaged, and the mother still in fair condition and uninfected. In some instances these objections might be set aside in favor of Cesarean section.
9. Enlargement of the pelvis to meet the disproportion is accomplished by separating the symphysis, or preferably cutting through the body of the pubic bone, the first known as symphyseotomy and the latter variously known as pubiotomy, hebotomy, etc., but preferably called hebosteotomy.

I would not wish to say that any one of these methods is without its field of usefulness in some hands, but I should have to have a stronger indication for abortion and craniotomy than that a patient did not wish to submit to a fairly safe obstetric operation. The periods of pregnancy and labor are no times for a woman to prove a "quitter." I should say that she has no right to ask the life of the child that she may avoid hebosteotomy or a comparatively safe Cesarean section.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

Artificial premature labor is followed by a large fetal mortality and efforts at dwarfing the growth of the child may prove ineffective or harmful if effective.

Again our treatment in many cases begins only after labor has begun or long continued. The value of a long and forced labor in molding the head in cases of mild disproportion must be appreciated and yet the dangers of exhaustion of the mother and compression of the child's head must not be underestimated. The head floating above the pelvic brim after long-continued labor indicates a marked degree of disproportion in which version and high forceps are seldom, if ever, indicated, as they are murderous to the child. Cesarean section, with the improved surgical technic, holds a wide and increasing field of usefulness. That there have been errors none will deny. Much has been said about Cesarean section displacing hebosteotomy, they are not entirely competitive procedures they are complementary, each having a place of its own, yet with their fields overlapping.

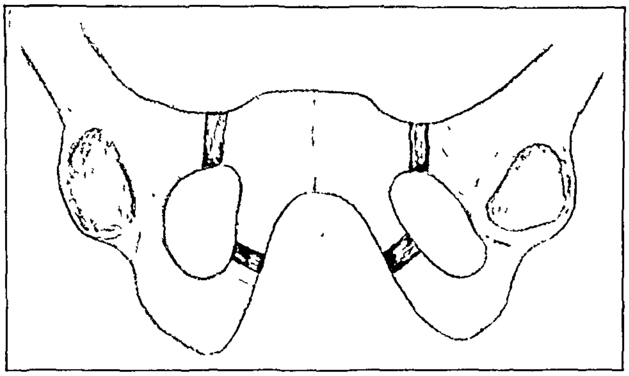

Fig 2.—Aitken's pelvitomy (1785).

Remove hebosteotomy, and craniotomy or its near cousins high forceps and version have to be substituted. Hebosteotomy is for the living child; craniotomy for the dead. A well-chosen Cesarean section promises life for the future child after the death of this one: hebosteotomy steps in to save this one. "Cesarean section gives a high percentage of recoveries." True, in selected cases; but done in those cases in which hebosteotomy could be successfully done the mortality would decidedly increase. Cesarean section permits of no well-determined efforts at labor in the border line cases with a safe means of escape if that effort fails. The statistics of Cesarean section and operations on the bony outlet cannot rightfully be compared as the former are done on fresh patients while the latter are frequently done on exhausted patients.

THE PLACE OF HEBOSTEOTOMY

I make no enthusiastic claim for the theoretic beauty of the operations of enlarging the bony pelvis, but if it saves life and in no great degree sacrifices health, it has a place, and if it has a place its successes will be greater as its indications are better understood and its technic improved. There is at present wide variations of opinion. The value and the place of the operation is not determined. Williams, who formerly spoke very discouragingly of symphyseotomy and in favor of Cesarean section, now reports his experiences based on 25 cases of hebosteotomy with marked success and this is entirely worthy of the consideration of the champions of Cesarean section who think that this should take the place of hebosteotomy.

RESULTS IN SIX CASES

My experience is based on six cases, the results of which have gone far to overcome my former prejudice against the advisability of attacking the bony pelvis. The six patients while operated on during varying *degrees of exhaustion have resulted in six living mothers* and six living children. Of these six cases four were seen after labor had continued for many hours. The patient in Case 4 had been in labor four and one-half days. The patient in Case 3 began labor under my care but was required to exert a strong test of labor because she had previously been delivered of a 9½ pound girl, with high forceps. She was urged to enter the hospital at the second delivery as it was found that the head was large and a moderate exostosis existed at the symphysis. The patient in Case 6 entered the hospital under my care and it was thought that delivery would take place. The test of labor and the use of forceps with moderate force disproved this. The patients in Cases 1, 2, 3, 5 and 6 had had forceps used previous to the operation of hebosteotomy. In Cases 2 and 3 and 6 the forceps were applied by myself and a very careful effort made to engage the head. In Case 5 the forceps had been applied several times before the patient entered the hospital, the head was arrested in transverse position. It was thought that delivery might be effected with the use of the forceps, but the child's heart-beats were so rapid and weak that it was not thought best to put the additional tax on it. Extreme efforts at resuscitation had to be used even after a very easy delivery by hebosteotomy. In this case the soft parts over each parietal eminence sloughed but with no evil after-results.

This, like many of the complications, must not be charged to the operation. In Case 4 the head could not be reached with any degree of safety for the application of the forceps. In three cases the hebosteotomy communicated, through more or less considerable tears, with the vagina. These were closed with drainage and in no way seem to complicate the healing of the bone. In no case were the tears more extensive than frequently happens without the operation, and Case 6, in which the patient had extensive vaginal tear due to necessarily wide separation, resulted not less favorably than those with less tear. In no case was there even annoying hemorrhage at time of operation or hematoma afterward.

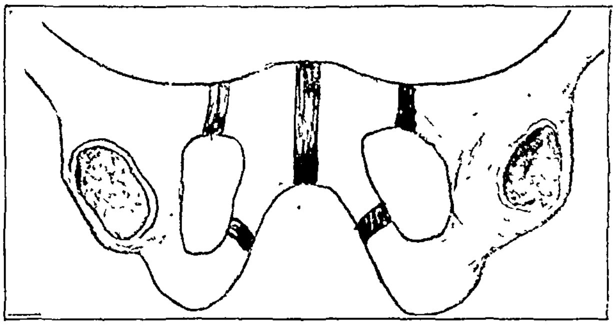

Fig. 3.—Galbiati's "pelviotomia," 1819-1832.

In Case 1 the operation was done in conjunction with Dr. Fitzpatrick by the open method. The Gigli saw was placed so far inward as to saw partly bone and partly cartillage. All others were done by the subcutaneous method and separated entirely through bone. The post-partum operation in Case 1 of bringing the bones and soft parts together consumed considerable time, while by the subcutaneous method all this was avoided.

The bony separation obtained we have estimated at from 3 to 6 cm. (about 1¼ to 2½ in.). Four of the patients have been recently inspected and in no case is there a waddling gait or difficulty in walikng due to the bony pelvis. The patient in Case 3 has some prolapse of the soft parts due to injury to the levator ani muscle; and the one in Case 4 has the cervix fixed by scar tissue but it is on the opposite side from that operated on and evidently in no way due to the operation.

COMPLICATIONS

Operators have recorded many evils and complications among which are injuries to the urethra, injuries to the head of the child, (laceration of the ear) traumatism of the iliac vessels, separation of the sacroiliac joint, severe hemorrhages (in some cases causing death) failure to obtain room for delivery even after this operation, non-union leading to disability, etc. These misfortunes have not befallen my patients thus far. It will also be seen that many of these are evils which may occur in case of severe labor without this or any other operation and many of them are plainly due to the injuries which have preceded the hebosteotomy or took place during delivery independent of the cutting of the bone. Direct injury to the bladder or to the head of the child have been due mostly to a sharp needle and this in itself must be looked on as faulty technic.

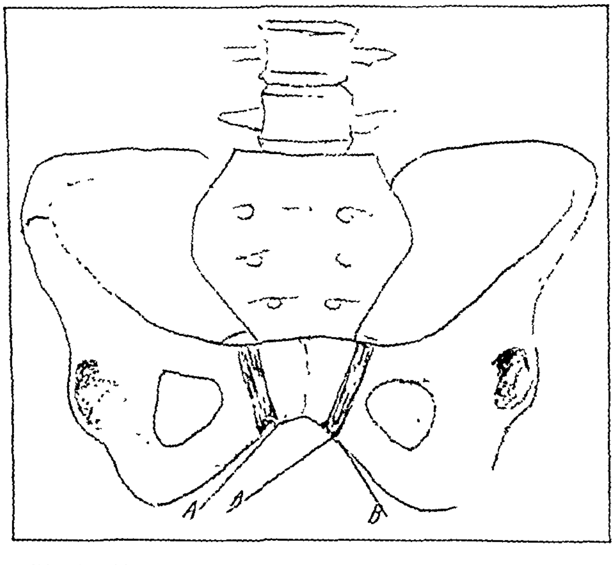

Fig. 4.—Diagram of (A, A') Pitois' bipubiotomy (1831), and (B) Champion's pubiotomy (1844).

In addition to the usefulness of hebosteotomy in immediate delivery it is interesting to determine the kind of healing that takes place as having some bearing on the future health of the mother and on future childbirth. In all cases examined the union has been firm, allowing no play of bone ends. In no case has there been a callous felt on the underside of the bone, but thickening has been felt on the upper surface persisting for some time. In four cases examined recently no thickening remains to suggest a previous operation. In one case a slight depression could be felt on the under side. There was, in all but one case, some fixation of the vaginal wall at the site of the operation. The skiagraphic picture has indicated a fibrous union in two cases but with separation of only ¼ and ⅜ inches, respectively. The skiagraphic results in the other cases were not satisfactory and future attempts will be made.

The above finding speaks well for the recovery of the patient but would seem to promise little so far as permanent enlargement is concerned. Williams reports the case of a patient dying after Cesarean section in a pregnancy following a hebosteotomy, in which a post-mortem study indicated a softening of the fibrous union that promised considerable enlargement. Some of his cases have shown enlargement and movability without apparent disability in locomotion. He reports, however, that such enlargement cannot always be expected as one patient had a second hebosteotomy with a child weighing even less. Seven of the pregnancies following the operation in his cases terminated as follows: 1 hebosteotomy, 2 Cesarean sections, 4 spontaneous deliveries.

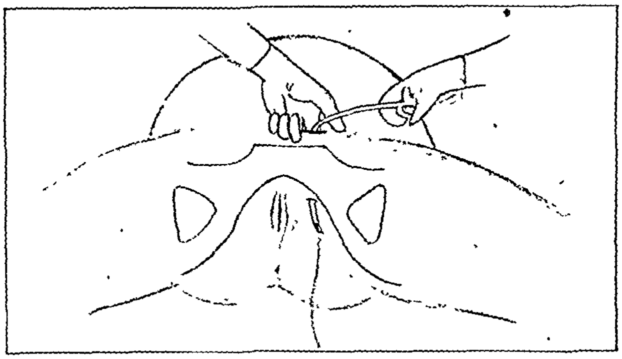

Fig. 5.—Döderlein's hebosteotomy, showing short transverse incision above the pubic bone for the introduction of the finger to guide the needle inserted from above downward.

It must not be taken for granted, however, that the cases of spontaneous deliverv were necessarily the result of permanent enlargement, for some of our patients had been previously delivered successfully. Neither must it be taken for granted that a patient having had a hebosteotomy is going to require operative delivery and a Cesarean section chosen, on that ground alone. Credé, Truzzi and Wendeler, Schikeles, Hammerschlag, Bell and others have advocated methods looking toward permanent enlargement, some even requiring extensive dissections.

When we consider that it is only in the slightly or moderately contracted pelves that hebosteotomy is applicable and in these cases the test of labor is needed to determine whether or not any enlargement will be required, and when it is so easy to get the desired enlargement at the time, if it is found necessary; and when we further consider that any permanent enlargement that would not cause a disability must necessarily be limited, while the required enlargement may vary 3 to 6 cm., such procedures must be viewed in the light of meddlesome surgery. I am convinced that our best results will be obtained by endeavoring to get the required enlargement for the present delivery with the best approximation and healing possible, leaving future deliveries to be determined by the merits of the case, spontaneous delivery if possible, forceps if required, hebosteotomy if necessary, Cesarean section if the degree of contraction is so great that delivery was very difficult with the previous hebosteotomy. To the extent that we get permanent enlargement, in that proportion shall we have disability in locomotion or pelvic hernias.

INDICATIONS

Lewis, in a summary of the literature, says: "I think the indications for both symphysiotomy and pubiotomy will become narrower and narrower as time goes on. In individual cases the decision will be between Cesarean section and perforation rather than between symphysiotomy and pubiotomy."

DeLee condemns hebosteotomy, but both these authorities speak without personal experiences with the operation, preferring Cesarean section. In many cases the opportune time for Cesarean section is past long before the life of the child is extinct—these authors would have to resort to craniotomy or, in these cases, a death-dealing high forceps or version. I think it may be said that the operation is indicated whenever it promises greater assurances of life to the mother and child than any other measure obtainable under given conditions. It can not compete with Cesarean section in marked degrees of contraction seen early. It has no reason to compete with craniotomy in the dead child. Neither can Cesarean section compete with hebosteotomy in patients who are seen advanced in labor and in whom numerous examinations and forceps applications have been made, making infection possible or, when the mother is exhausted. Yet in many of these cases craniotomy has no place, and version and high forceps are scarcely better.

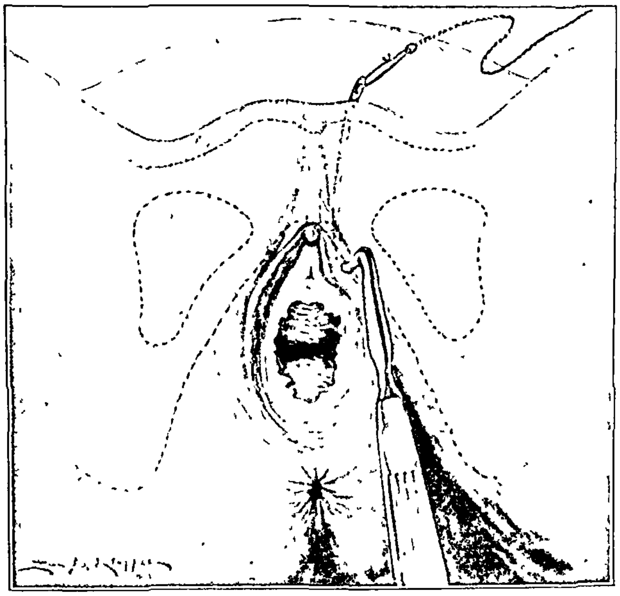

Fig. 6.—Hebosteotomy, showing the author's needle in place, entering just under the body of the pubic bone and emerging just above the bone and inside the pubic spine. The silk carrying the saw is then double threaded or tied in the eye of the needle.

It must be said that under these conditions hebosteotomy is not at its best but is not precluded, and may be said to have a wide field. Its most ideal field is in those cases in which a moderate degree of contraction foretells a difficult labor but in which there is promise enough of delivery that a good strong test of labor is desired. Here the patient should be placed under the best of surroundings and progress awaited. Should the mother or child show exhaustion, speedy delivery may be obtained at any time. I have not chosen the prophylactic hebosteotomy, for experience has shown that had I been so inclined I would have performed the operation on patients who were delivered spontaneously, or with forceps. On the other hand I recall a number of cases in former experience in which I should now employ hebosteotomy. Some place the aseptic restrictions on hebosteotomy almost or quite as strong as on Cesarean section. While it is true that sepsis complicates any operative procedures and that complications will increase thereby, yet the mere possibility of sepsis is no contraindication to the operation, and it must be remembered that the infected woman is not safe with or without operation, and instances may arise in which the saving of the child will more than offset any slightly increased risk to the mother incident to such operative procedure.

HISTORY

Hippocrates recognized the disproportion between the child's head and the pelvic outlet and its tendency to cause malposition. His writings also express the belief that delivery is effected by a separation of the pubic bones and that this should be permanent making future childbirth easy. Only the dangers of surgery would prevent this conception from being utilized in enlargement of the pelvis during difficult labors. Hebosteotomy can only be said to secure the advantages of symphyseotomy minus some of its disadvantages, and therefore the history of the two is closely associated.

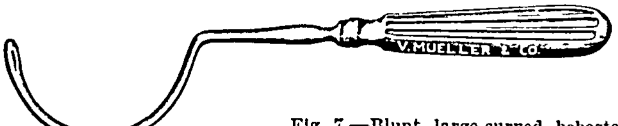

Fig. 7.—Blunt, large-curved, hebosteotomy needle, two-fifths size.

Sigault first demonstrated the possibility of pelvic enlargement by means of separation of the symphysis in 1768 but he lacked opportunity to demonstrate it on the living until 1777 when he and LeRoy operated on Mme. Suchot, who had had four difficult confinements with no living child. This resulted in a living child. Antonio Delgado in 1781 published an account of an operation of separating the symphysis with a knife subcutaneously, great enthusiasm was shown for symphyseotomy but it met in Baudelocque a caustic opponent. Misjudgment and lack of skill led to its falling into disrepute for nearly a century, when it was revived in 1866 by Morisani, who in 1881 reported 50 operations with 40 recoveries. Spinelli and Pinard are credited with its introduction into France.

R. H. Harris called attention to its use in this country, but Jewett was the first to perform the operation on this side of the Atlantic. Numerous methods of enlarging the pelvis were proposed in the century following Sigault's work. Pitois in 1831 proposed "bipubiotomy," severing both pubic bones. Champion proposed restricting this to one side in 1844. Aitkin in 1785, proposed "pelvitomy," cutting into the obturator foramen on each side severing all rami of the pubic bone. Galbiati's "pelviotomia" in 1819 to 1830 extended this to include the separation of the symphysis, but evidences are lacking that these operations were performed except on animals. Gigli in 1894, after a study of the disadvantages of symphysiotomy, proposed the cutting of the pelvic bone through an incision; this was but carrying out the idea of Champion fifty years previously. Bonardo of Lugano was the first to perform the operation in 1897. Calderini, Van de Velde and Gigli soon followed. Doederlein in 1904 substituted a small incision through which the tip of the finger could be inserted, to guide the needle posterior to the pubic bone. Walcher and Bumm punctured the skin and carried the needle through without the introduction of the finger. Montgomery of Quincy, Ill., was the first to do pubiotomy in this country, and recommends the Gigli incision, claiming to see no advantage in the subcutaneous operation. My observation would lead me to a far different conclusion.

CHOICE OF METHOD AND TECHNIC

As a means of enlarging the pelvis, hebosteotomy must be compared with symphysiotomy, the older operation. Each procedure has its supporters but there is a growing consensus of opinion that hebosteotomy secures all the advantages of the other operation minus some of its objections. Comparisons of statistics are drawn from a period when operative technic was less perfect, and again the statistics of symphyseotomy are largely with the open operation while hebosteotomy statistics show improvement because of the use of the subcutaneous, or partially subcutaneous, method. It may be said that hebosteotomy requires special instruments which may not be at hand; it is urged, however, that hebosteotomy runs less risk of injuring the crus, the urethra and the bladder, and, being through bone, secures better union. While not favoring symphyseotomy I am free to admit that its record might be decidedly improved if the subcutaneous method were adopted.

If hebosteotomy is chosen we then have for consideration the open method of Gigli, the partially open method of Doederlein and the subcutaneous method of Walcher and Bumm. My very limited experience of one case with the open method, and five cases with subcutaneous method leads me greatly to prefer the latter. There is no comparison in ease of performance and simplicity of after care. Montgomery, Williams, myself and others have chosen the open method for the first operation. Montgomery without further experience says he sees no advantage in the subcutaneous method. In Williams' subsequent cases the patients were operated on by the partially subcutaneous method of Doederlein and he much prefers it to the open methods. He has not tried the entirely subcutaneous method and thinks that his success in avoiding the bladder is due to the use of the partially open method. He, however, ascribes some of the infections to the open method and thinks it possible to avoid this by having a clean assistant close the wound.

There seems to me great advantage in the subcutaneous method providing a safe means of avoiding the bladder can be obtained. In the subcutaneous methods of Walcher and Bumm a sharp needle is employed that punctures the skin. The needle which I have had constructed has a large curve which gives plenty of room to sweep around the pubic bone, even though massive—as many of them are—and still allow for abundance of adipose tissue. The needle not only offers safety to the bladder directly by reason of its bluntness but, being blunt, it can be made to grate against the bone without catching unduly and thereby avoiding contact with the bladder. If this precaution is observed the point of the dull needle is under control at all times. It will be seen that the sharp needle cannot scrape the bone and therefore may injure the bladder. The needle enters through a slight knife stab at the fissure between the labium majus and minus at the lower border of the body of the pubic bone, is made to scrape the posterior surface of this bone to its upper border, when the handle is depressed and the point made to elevate the skin above the upper border of the bone where it is brought out a slight knife puncture. During the journey of the needle, its direction is controlled by one or two fingers in the vagina. When the needle is in place it is threaded with heavy silk thread, which carries the Gigli saw, after which it is made to retrace its steps, leaving the saw in place to sever the bone. The time of performing the operation is a matter of some discussion. Some Continental writers prefer to perform the operation early in labor after which the labor is allowed to progress normally. Four of my cases were seen after the patients had been long in labor and in the other two I needed the strongest test of labor and the moderate test of the forceps to prove the necessity of the operation, so that in all cases immediate delivery was desirable or imperative, which has been accomplished in each case with forceps. Possibly podalic version might be employed to advantage in some cases looking to a better adaptation of the head, as posterior positions are common. Forward rotation has been possible in all cases.

With Williams, I have found it a great advantage to massage and stretch the vagina and pelvic floor previous to the introduction of the saw, but this is scarcely less desirable in forceps delivery and so cannot be counted as belonging to the hebosteotomy. The technic, in addition to the forceps delivery, is the introduction of the needle and the sawing of the bone with perhaps the sewing of an unusually placed tear. Some have recommended the laying of the saw preliminary to the application of the trial of the forceps but this would mean an unnecessary laying of the saw in some cases. It appears more desirable to make the required test with the forceps, failing in which, the forceps may be removed and the hebosteotomy performed after which the forceps may be reapplied. On the other hand, I do see great advantage in the preliminary preparation of the saw if a breech delivery or podalic version is to be attempted in cases of disproportion, as when once begun, time would not allow the introduction of the needle even if necessary to delivery, while if the introduction had taken place the bone could quickly be severed. I would here recommend the introduction of the silk carrying the saw, leaving the saw above, as this would avoid the hard rough saw between the head and the pubic bone. If delivery failed, the saw could be quickly drawn through.

The after care has been very simple in the patients operated on subcutaneously. A sand-bag has been placed on each side of the patient and a broad adhesive strap placed across the pelvis in front. In cases in which a vaginal tear occurred this was closed and a strip of gauze carried up to the bone for a few days.

MORTALITY AND MORBIDITY

Hebosteotomy is an operation of importance undertaken at times when the mother or child has undergone considerable strain and sometimes abuse. It is inevitable that it will have a mortality and morbidity but these are often the results of prolonged labor not due to the operation but due to the operation being delayed. It is an operation of weight whose dangers are hemorrhages, infection, injuries to the soft parts, etc., all the details of which cannot be discussed. It will have its greatest percentage of success in the hands of men not only trained in surgery but trained in obstetric surgery of this particular kind. It will have its greatest numerical success, although some failures, when taken to the lying-in room by all who are willing to be taught the technic and to provide the necessary saw and needle. It is not technically as difficult as repairing a lacerated pelvic floor, but that is not saying that it has no difficulties. I am inclined to think that Reed puts the matter too lightly, yet any procedure that will advance the obstetric art greatly must be capable of application by the many. Schlafli and others are overconservative. It is our purpose and privilege to say what is to be done with a woman advanced in labor with a living child in the presence of disproportion; it is the individual worker's problem to answer the question as to his ability to carry this out in his environment.

In conclusion I would say:

1. Pregnancy fails of its fundamental purpose when it does not terminate with a living child and living mother.
2. The child has rights that the mother's wishes and convenience have no right to ignore.
3. Patients should be examined for disproportion previous to the time of delivery and if this condition is present the child and mother should be safeguarded by being placed under the best possible conditions.
4. Hebosteotomy gives a separation of 3 to 6 cm. and facilitates delivery in cases of moderate disproportion to such an extent that the mortality and morbidity to the child and mother is only slightly greater than that incident to the injuries already sustained.
5. Hebosteotomy has a field in place of craniotomy in the living child showing an improved fetal mortality of nearly 100 per cent. with slight, if any, increased mortality to the mothers.
6. It should not be elected in place of Cesarean section in patients with a true conjugate of less than 7 cm.
7. It has a wide field of usefulness in those borderline cases of patients who fail to deliver after a strong labor test.
8. A head floating above the pelvic brim after a sharp second stage indicates such a degree of disproportion as to make version and high forceps dangerous.
9. Hebosteotomy has a field in the above condition after a moderate trial with the forceps or in cases in which they cannot be conveniently and securely applied.
10. When hebosteotomy is employed after labor has long continued, the patient should be delivered immediately with high forceps or version.
11. Version should not be employed in cases with marked disproportion without a preliminary laying of the silk which is to carry the saw.
12. The simple instruments necessary to this means of saving human life should be a part of the obstetric outfit.

100 State Street.

ABSTRACT OF DISCUSSION

Dr. Ernest G. Zinke, Cincinnati: When advocating hebosteotomy, two years ago, before the American Association of Obstetricians and Gynecologists, I found but little sympathy, and this operation was roundly denounced at a meeting of the American Gynecological Society two years ago. With the exception of Montgomery of Quincy, Ill., Williams of Baltimore was the only one, at that time, who had performed the operation repeatedly, notwithstanding the opposition expressed. The new therapy of narrow pelvis simply implies this. We must carefully study pregnancy cases before parturition sets in. If we discover contracted pelves, these patients should be conveyed if possible, to a lying-in hospital. When the pelvic contraction is moderate, the "test of labor" is indicated. If the passage proves too small for the passenger, the case is one either for hebosteotomy or Cesarean section. If the contraction of the anteroposterior diameter of the inlet is not below 8 or 7.5 cm., hebosteotomy is indicated, if the contraction amounts to 7 cm. or less, the case is one for Cesarean section. The new therapy of narrow pelvis has achieved wonderful results abroad, principally in Germany, Italy and France. There are on record several thousand cases of narrow pelvis in which this new treatment secured a maternal mortality of only 0.1 per cent., and a fatal mortality of between 4 and 5 per cent. What better results can we expect? Briefly stated, the new therapy of narrow pelvis at present consists of the test of labor, hebosteotomy and Cesarean section. Eighty per cent. of the women subjected to this treatment delivered themselves spontaneously without harm to themselves or their offspring, 15 per cent. were delivered by the aid of hebosteotomy, and only 5 per cent. required Cesarean section. Equally good results have never been obtained by other means in the history of obstetrics.

Dr. Collin Foulkrod, Philadelphia: I think it is unwise to let this paper pass without saying a word from the standpoint of those few men who, Dr. Barrett says, still hold to some other views not supporting hebosteotomy. In the institution with which I am connected, we have not done it, because we have been able to save the patients without doing hebosteotomy, and because we have been led by the experience of other men to conclude that perhaps hebosteotomy does not fill the place it is said to fill. I think that men going out into the country should know something of the objections to it. In the first place some of these patients should be subjected to the test of labor, but this consists in proving without forceps whether it is possible for the head to engage in the pelvis. If it can, there is no question of doubt that we can bring the head out with forceps. In the class of cases in which the head cannot engage, we do not manipulate enough to have them called infected cases and in these Cesarean section is done with good results, there being less than 1 per cent. of deaths to the mother, with 100 per cent. of living children. These cases are not in our own practice, because in our own patients we determine by measurement made before labor whether Cesarean section will be needed, but there come to us in hospital work certain cases that have been handled, and they are dealt with according to the indications, we have saved as great a percentage with Porro Cesarean section as with hebosteotomy. There are still a few men in the large cities who hold to the view that patients can be delivered by Cesarean section after a fair test of labor. Those who go out into practice should study cases to know whether to induce labor rather than do hebosteotomy. Hemorrhage is present in some cases, and unless great precaution is taken there will be failure to control it. In the second place, there will be greater lacerations by hebosteotomy than by Cesarean section in good hands. Hebosteotomy has a place in obstetrics, but the cases in which it is applicable are very few.

Dr. H. D. Fry, Washington: I expect that I am to blame for the objections that were made to this operation which Dr. Zinke refers to in connection with the American Gynecological Society three years ago. I read a paper at that time reporting some cases, and also the histories of patients who had been operated on in this country. The great objections to hebosteotomy as shown by that paper were, that there were a number of cases of lacerations from the incision into the vagina and injuries to the bladder. There were cases of hematoma, of septic inflammation and of phlebitis and in one of the cases that I reported, the patient died on the tenth or eleventh day from embolism due to septic phlebitis. These lacerations of the vagina and injuries to the bladder are not due to the use of the needle or knife, but to the tearing of the tissues when the head, on extraction, causes separation of the bones that have been sawn apart. Another great objection to hebosteotomy and symphysiotomy is that convalescence is so unsatisfactory. The patients suffer a great deal of pain, it is difficult to draw the urine and the nurses dislike the care of these patients. I have tried repeatedly to have a special bed used, having a hole cut at the point where the buttocks will come, so that the douches may be given readily. I dread to do the operation, simply because of the unsatisfactory convalescence. I believe, however, that there is a place for symphysiotomy or pubiotomy, but I would never make the operation an elective one, as has Williams, who has done it in 25 cases, nearly every one elective, in which I should have performed Cesarean section. The patients I would treat by this operation are just the ones Dr. Barrett has mentioned. If I were called to see a woman who had been in labor for some hours, examined repeatedly, and on whom the forceps had been tried, Cesarean section should not be done. In such cases we must resort to hebosteotomy or craniotomy, version or high forceps. Craniotomy I do not believe is justifiable on the living child. High forceps operation in maternity hospitals has a death rate among children of 33 per cent. Version with contracted pelves has about the same fatality, so in those border line cases, in which we have had labor coming on, or those in which we have allowed labor to come on as a test, if the head is still not engaged and the case has the appearance of a difficult high forceps one, the time for doing a hebosteotomy has arrived.

Dr. T. Mitchell Burns, Denver: I wish to speak for symphysiotomy, not saying that hebosteotomy is not just as good. I believe to the average obstetrician symphysiotomy is a simpler operation, requires no special instruments, and gives just as good, if not better, results. I have performed this operation four times on parturient women, have operated once on the cadaver and another time on the dog. I believe preliminary operations should be done on the cadaver and the dog before one operates on the human being. In the cadaver I did not cut completely through the sub-pubic ligament, and as a result I had laceration of the clitoris. I believe that symphysiotomy or hebosteotomy may be well performed in the private house. This makes it a much better operation to consider in a great many cases in the country. All that is necessary to hold the hips together afterward is an ordinary many-tailed bandage. All the complicated apparatus is absolutely unnecessary. The patient's posture may be lateral or dorsal, or with the legs extended or flexed. She may get up at the end of two weeks or ten days even.

Dr. Channing W. Barrett, Chicago: The champions of Cesarean section did not come out so strongly as I thought they might. There was much in the paper that I would like to have brought before the Section, which I did not have time to read, and some of these points have been mentioned. One point is, that in enlarging the pelvis we have different procedures to fall back on, one of which is symphysiotomy and the other pubiotomy. The advantages of the pubiotomy are perhaps less risk of injury to the urethra, and bone union instead of cartilage union. One of the advantages of symphysiotomy, as Dr. Burns stated, is that it may be done without the instruments necessary for hebosteotomy in an emergency, and the disadvantages of symphysiotomy as taught in literature are not so great as the statistics would indicate, because the statistics of symphysiotomy are drawn from an older period than those of pubiotomy—a time when the technic was less accurate, and the statistics compare open symphysiotomy with subcutaneous hebosteotomy. If we could compare the statistics of subcutaneous symphysiotomy with subcutaneous hebosteotomy we might find that the statistics would be almost as good as they are in hebosteotomy. Some authors insist that the open method of one should not be compared with the subcutaneous method of the other. Subcutaneous hebosteotomy has much the advantage over the open method in the immediate time of doing the operation, the element of danger to the patient, after-care, etc. Dr. Fry spoke of the precaution of having the patient supported from the side. I find that entirely unnecessary. When we cut through the bone we get just a little separation, because we have all the soft parts there to hold the pelvis. If an open operation were being performed we might need to observe this precaution. In the subcutaneous operation it is only when we draw the head through the pelvis that we get such separation as is required.

The point was made in regard to Cesarean section that the cases were chosen—that the physicians determined beforehand by measurement whether the head was going to come through the pelvis or not. They must have a very fine technic. There are some cases in which measurement would easily determine that a Cesarean section would be necessary, but that is not the average case. More frequently it is the border line cases we meet in which a strong labor test is required to determine this. I have had opportunity to observe cases in which measurement determined that a Cesarean section would be necessary, but labor easily proved the contrary by spontaneous delivery. A slight test of labor is no test at all, it takes a very hard test to tell whether the woman is going to deliver herself spontaneously or with forceps, after which a Cesarean section may not be advisable. We see also cases in which the patients have been in labor under the hands of some one else, and they have passed the time when safe Cesarean section could be done. In hebosteotomy we have an operation that an average man can do.

Williams says, that in cases in which he is going to put on forceps or perform version, he would put the saw in position so that if version or forceps failed he could sever the bone. This is unnecessary in case the forceps are to be applied, because if the forceps fail we can take them off and then introduce the needle and saw. In version this precaution is important, but I would urge the advisability of introducing the silk that is to carry the saw rather than the saw itself, as we will not then have the rough saw between the fetal parts and pelvic bone, while if efforts at delivery fail the saw can readily be drawn through. My experience has not demonstrated that the patient has marked pain after this operation, nor that the after-care is formidable, as has been mentioned by Dr. Fry.

INFLUENCE OF PERIGASTRIC LESIONS ON GASTRIC SECRETIONS

STUDY BASED ON CLINICAL AND EXPERIMENTAL OBSERVATIONS

M. J. LICHTY, M.D.
CLEVELAND

A few years ago I was impressed with the extraordinary frequency with which I met patients who had gastric hyperacidity with their gastric symptoms. Many of them were of a neurotic type and could possibly have been diagnosed and dismissed as cases of nervous dyspepsia with hyperacidity. But a great many others, eventually and often surprisingly, gave positive symptoms and physical signs pointing to disease of other organs near the stomach, which, no doubt, influenced the gastric secretions and made the diagnosis of nervous dyspepsia unwarranted. In a discussion of this matter with my brother, Dr. J. A. Lichty, of Pittsburg, I found that he had the same experience. On account of the belief that the very frequent diagnosis of dyspepsia with hyperacidity was often unwarranted, we decided to investigate the subject more minutely, both from clinical observations and by experiments on animals.

SUMMARY OF CLINICAL OBSERVATIONS

In a review of the cases of 600 patients who consulted me in private practice, who complained of symptoms referring to the stomach, and on whom gastric analyses were made, 318, or more than 50 per cent., had a gastric juice which was hyperacid. The number of cases with normal acidity, subacidity and achylia gastrica was less than those of gastric hyperacidity. This excessive acidity could be accounted for in several ways. Some were cases of simple nervous dyspepsia with hyperacidity. Many could safely be diagnosed as catarrh of the stomach with hyperacidity. A considerable number of patients had ulcer of the stomach. But others had a hyperacidity which, from what the clinical and experimental work now indicate, was secondary to lesions of the digestive tract in organs surrounding the stomach.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

I regret that my own tabulated report of very positive diagnoses of appendicitis and gall-bladder disease is so limited. It may be worthy of mention, however, that, in 54 per cent. of the fifty-six cases of acute and chronic appendicitis seen the last few years in private practice, examinations, including gastric analyses, were made. And, of the cases in which these gastric analyses were made, 83 per cent. showed a hyperacidity. In nearly all of the cases diagnosed as appendicitis the advice for operation was warranted, but only 65 per cent. of these cases were treated surgically, three-fourths of which had gastric analyses which showed a hyperacidity in 75 per cent. of the analyses. It appears, therefore, that of the patients operated on, as well as in those not operated on, more than 75 per cent. had a gastric hyperacidity.

In a still more limited number of gall-bladder cases (forty in all), 75 per cent. showed a gastric hyperacidity and, of those gall-bladder cases in which the diagnosis was verified by operations, more than 50 per cent. had a gastric hyperacidity. Those gall-bladder cases studied at operation which showed up hyperacidity were peculiarly interesting, inasmuch as they quite universally showed a gastric secretion with the very opposite extreme, a marked hypo-acidity. This hypo-acidity was usually present when the patient's physical condition had been greatly reduced by prolonged illness, or by extensive adhesions which bound together both stomach and gall-bladder, interfering directly with the motor power of the stomach. Two of the operative gall-bladder cases with subacidity had most striking gastric symptoms. The gastric analysis showed a marked deficiency of acids, the presence of lactic acid, as well as occult blood in several repeated analyses, making one very suspicious of gastric carcinoma. But the operations in these two cases showed nothing but gall-stones, and a perfectly healthy stomach except for adhesions to it. Another gall-stone case, with hypo-acidity and a secondary anemia, so marked that the diagnosis of some form of serious primary anemia was considered, had most dense adhesions between the gall-bladder and stomach, as well as an old perforation of the gall-bladder, which allowed the escape of several small stones into the peritoneal cavity. These stones, however, had been held adjacent to the gall-bladder by the firm adhesions.

Reference must here be made to the very striking similarity of figures and percentages in a study of a greater number of cases taken from the records of Dr. J. A. Lichty. Gastric analyses performed in 111 out of 258 of his cases of appendicitis showed a hyperacidity in 64 per cent. of the analyses. Of his 127 patients subjected to operation only forty-nine had had a gastric analysis, but in 69 per cent. of the cases a gastric hyperacidity was present, showing, therefore, a hyperacidity in two-thirds of all appendicitis patients so examined, whether operated on or not operated on. In 157 of 250 gall-bladder cases, which he tabulated, gastric analyses showed a hyperacidity in 54 per cent. of analyses; and, in those gall-bladder cases treated surgically in which gastric analysis had been made, 53 per cent. had an excess of gastric acidity.

Similar study of the gastric juice has been made recently by others:

Graham,[1] in his work with the Mayos, has very recently referred to the gastric symptoms arising from surgical conditions of other abdominal organs, though it was not his experience to notice this frequency of gastric hyperacidity.

Paterson,[2] of London, only a few months ago, expressed his surprise at the frequency of gastric symptoms and the change in gastric secretions caused by appendicitis. In his opinion, the many symptoms of gastric ulcer and even gastric hemorrhage were found at times, by study as well as at operation, to be the sequel of appendicitis. In a few of his cases there was a normal acidity, in about 30 per cent. a hypo-acidity, and in the remaining a marked hyperchlorhydria. He says that "a combination of marked symptoms of gastric ulcer with a negative gastric analysis is suggestive of chronic appendicular disease," and that "in recent years it is becoming gradually recognized that hematemesis, accompanied by pain and vomiting, is not pathognomonic of gastric ulcer." His statement that a gastro-enterostomy will not remove a diseased appendix is strikingly significant. While my experience is not exactly parallel with that of Paterson, since mine shows appendicitis frequently with a positive change in gastric secretion instead of a negative gastric analysis, as he states, yet I am very happy to refer to his comment of associated symptoms.

Here I wish to refer to a patient of my own who, three years ago, had a gastro-enterostomy for a gastric ulcer, which was nearly perforated and was excised at operation. Another ulcer was found to be present at the same time. The operation was done hurriedly. The patient made only a fair recovery and required an entero-enterostomy a year later to correct a vicious circle. Previous to the first, and following the second operation, the patient's gastric secretions were high, but within the last year she again developed vomiting and there was occasional blood in the vomitus. The tenderness over the appendix, which had been noticed the last few years, became more marked and the appendix was removed from dense adhesions only a few months ago. At present the patient seems to be making a good recovery.

W. S. Fenwick[3] calls attention to a mild type of hypersecretion, the result of latent disease of the appendix. He says:

> As a rule, it displays an intermittent character for several years and each fresh addition is ascribed by the patient to a chill, mental anxiety, or some indiscretion of diet. Considerable time after it has attained the chronic stage, the typical symptoms of a moderate hypersecretion continue to manifest themselves, but, with the progress of time, paroxysmal pain is gradually replaced by discomfort and distention, which persists during the day, the symptoms varying to a great extent according to the appendicular lesion and the concomitant state of the gastric secretion.

Moynihan[4] states, that, in his view, "the typical gastric ulcer in the medical text-book is frequently the appendix." In his study, recently published, he considered the pathology and symptoms of the associated lesions of the appendix and stomach without giving much attention to the gastric secretions. I myself believe that the typical chronic dyspepsia (of the medical text-book) with change of gastric secretions is frequently the appendix or the gall-bladder.

EXPERIMENTAL OBSERVATIONS

A summary of earlier clinical observations, as well as those of others more recently made, has fully justified an investigation of this subject from an experimental basis. Experiments on a number of dogs were begun two years ago and have been continued constantly since, with some very satisfactory and surprising results. The method of experimentation, briefly described, was as follows:

---

[1] Graham, C., and Guthrie, D.: The Dyspeptic Type of Chronic Appendicitis, The Journal A. M. A., March 19, 1910, p. 960.

[2] Paterson: Appendicular Gastralgia in Appendicitis as a Cause of Gastric Sypmtoms, Lancet, London March 12, 1910.

[3] Fenwick, W. S.: Lancet, London, March 12, 1910.

[4] Moynihan: Brit. Med. Jour., Jan. 29, 1910.

A number of healthy dogs were secured and a study was made of their gastric secretions. At definite intervals of two or three days the dogs were not fed until noon; then a meal of about 8 ounces of water, containing bread sufficient in quantity to make a gruel, was inserted into the stomach with a bulb and a stomach-tube. Thirty minutes later, this meal was removed and analyzed. We soon found that, if the bread and water remained in the stomach much longer than thirty minutes, the stomach was empty and the secretions and acids were low. In other words, the gastric secretions in dogs supplied with practically the Ewald meal were at the highest about thirty minutes after feeding. After a dozen or more test meals were given to each dog, and a fairly accurate average estimation could be made of the gastric secretion, these dogs were subjected to laparotomy. At the first operations the gall-bladder was opened and filled with cinders and pebbles. Then, again, about a dozen or more analyses were made. After that period, the dogs were operated on a second time, at which time the appendix was opened and filled with foreign bodies, which were fixed there with sutures. The appendix in the dog is, of course, rather a diverticulum of the cecum than a real appendix as in man. After the operation on the appendix, a third series of gastric analyses was made. Following these operations and analyses, if death had not occurred, a third laparotomy was performed, or the animal was bled to death in some other experiment and a post-mortem examination was made to see what pathologic conditions had been caused by the former operations. Out of a number of dogs secured for these experiments, only seven survived all this analytical work and all these surgical operations.

The information which we have gained from these surgical operations, fifteen in all, and from the gastric analyses, exceeding 500 in number, is in our estimation worthy of consideration. Though only seven dogs were kept for any length of time, and subjected to operations with gastric analyses before and after, several dogs were kept under observation and subjected to analysis only. We soon found that the study of these numerous test meals was of no value or constancy, unless done with much caution and care. Even then, there was considerable variation in the gastric acidity, which indeed was the only secretion studied, including free hydrochloric acid, combined hydrochloric and total acidity.

When the dogs were given the Ewald meal at noon, as previously described, and then fed again with meat and other food soon after the Ewald meal was removed, but not any oftener that day, there was a fairly constant acidity. If, however, the dogs were fed oftener and excessively the remainder of the day, the following day the acids were higher, even though the test meal given at noon was the first food of that day. On the contrary, we also noticed that, when the dogs were starved for forty-eight hours and then given the test meal, the acidity was constantly and markedly very much lower. This notice of a hypo-acidity after hunger or starvation came in a peculiar way. At one time daily analyses were begun on six new, healthy dogs. After several analyses were made on each one it was suddenly noticed that on alternate days the acids were high one day and very low the next. The variation was so great and constant that the physicians who made all the analyses could not overlook or explain it, until they found that, by some misunderstanding of the man who fed the dogs, the animals were given food after the removal of the test meal only every second day. They were then very hungry and ate much. The day following such a full meal the acids were generally high, but the second day thereafter, without any food for forty-eight hours, they were just as constantly low. At another time we secured several new dogs, on which gastric analyses were impossible or of little value, except for one point, the influence of excitement on the secretion. While most of the dogs usually took the stomach-tube and test meal without any difficulty, these dogs fought such a procedure stubbornly. Very rarely could we recover a meal from these dogs. If taken at all, it had to be taken promptly at the end of half an hour; then it was very acid. Sometimes the animal fought the introduction of the tube and meal so stubbornly that vomiting and diarrhea immediately followed. These dogs were not kept long, though long enough to make us believe that excitement caused increased acidity and peristalsis.

A summary of the analytical work done on three dogs only will be given.

Dog 1.—This dog had eight analyses before any operation, in which the average gastric total acidity was 60. At his first operation the gall-bladder was filled with pebbles. This was followed by sixteen analyses, giving an average total acidity of 54. At a second operation on the dog the appendix also was filled with pebbles, which were held in place by purse-string sutures. The gall-bladder was examined at the time and found to be contracted and adherent to the liver. The stomach was free. The second operation was followed by nineteen gastric analyses, with an average total acidity of 75. At a third operation the appendix was found to be somewhat adherent to the bowels, but not entirely obliterated. More foreign bodies were placed in the appendix and this operation was followed by twenty-six analyses, with an average total acidity of 72. When, later, the animal was bled to death, many adhesions were found around the appendix, gall-bladder and intestines though the stomach was free from adhesions. The acidity had risen 25 per cent.

Dog 2.—This dog had seven gastric analyses, with an average total acidity of 43. The gall-bladder operation was followed by eight analyses, with an average total acidity of 42. This, again, was followed by an operation on the appendix and examination of the gall-bladder. This last operation was followed by eighteen analyses, with an average total acidity of 57, the last series of examinations showing an increased total acidity of 30 per cent. This dog, however, died from intestinal obstruction, and the last six analyses showed a gradual lowering acidity. At post-mortem examination it was found that dense adhesions about the appendix and bowels caused intestinal obstruction and death. It will be noticed, therefore, that, in spite of the gradual lowering of acidity in the last six analyses prior to death, the last series of examinations, including the last six, had an increased acidity.

Dog 3.—This dog had thirteen gastric analyses, with a total acidity of 92. This was followed by an operation on the gall-bladder, filling the gall-bladder with pebbles. Eighteen analyses were then made, showing an average acidity of 82, a reduction of ten points. At a second operation the appendix was filled with pebbles and the stomach was found adherent to the gall-bladder and abdominal wall. Thirteen analyses were then made, with an average total acidity of 56. When the dog was finally bled to death, dense adhesions were found binding together the stomach, gall-bladder, intestines, appendix and omentum, and even the abdominal wall. This dog, therefore, showed a diminution of total acidity from 92 to 46, almost 40 per cent. The extensive adhesions certainly interfered with the gastric function.

32401

mental work now indicate, was secondary to lesions of the digestive tract in organs surrounding the stomach.

I regret that my own tabulated report of very positive diagnoses of appendicitis and gall-bladder disease is so limited. It may be worthy of mention, however, that, in 54 per cent. of the fifty-six cases of acute and chronic appendicitis seen the last few years in private practice, examinations, including gastric analyses, were made. And, of the cases in which these gastric analyses were made, 83 per cent. showed a hyperacidity. In nearly all of the cases diagnosed as appendicitis the advice for operation was warranted, but only 65 per cent. of these gastric [illegible] surgically, three-fourths of which had acidity. It will be noticed [illegible] hyperacidity in 75 per work, though not as extensive as we [illegible]fore, that of the two features very similar to the clinical [illegible]perated on, namely, a decrease of gastric acidity following [illegible] mation, shock or impaired gastric motility, and an [illegible] crease of gastric acidity when the function of the perigastric organs only was impaired by adhesions and the stomach left free.

Bashford, at the head of the Imperial Cancer Research Laboratory, in London, reports the findings of the gastric analyses of 500 mice inoculated with cancer. Most of the mice inoculated, of course, had cancer in organs not affecting the stomach. The analyses of these 500 mice showed a gastric hyperacidity. The hyperacidity could be explained only as a compensatory feature. This gastric hyperacidity of mice afflicted with cancer not affecting the stomach is quite a contrast to the hypo-acidity found in human beings afflicted with cancer affecting the stomach.

It will be noticed that this study of gastric secretions was not made on animals with the Pawlow fistula, inasmuch as the establishment of the Pawlow fistula, though ideal for certain studies of gastric secretion, would have required some adhesions between the stomach and the abdominal wall, which alone would have made rather indefinite a study of the influence of adhesions affecting the other organs, which concerned us more especially.

The terms "perigastric lesions" and "perigastric organs" have been used merely to avoid the more technical and frequent reference to the many abdominal structures and pathologic conditions either very close to or more distant from the stomach. There is no doubt that the functions of the liver, spleen pancreas and uterus, when changed by disease, have an influence on the stomach also.

CONCLUSIONS

It seems to me that this clinical and experimental study warrants the conclusion that the frequent diagnosis of nervous dyspepsia with hyperacidity should not be dismissed as a neurosis without caution. Likewise, many cases of hypo-acidity, even when occult blood and lactic acid are present in the gastric secretion, often demand an explanation beyond the stomach itself.

A summary of the experimental work showed, (1) a decrease of acidity during starvation; (2) an increase of acidity following excitement; (3) a decrease of acidity from lesions causing inflammation and shock and greatly impaired motility; and (4) an increase, perhaps compensatory, when the function of the perigastric organ is impaired by adhesions. While this study, of course, is not conclusive it is reported simply as a matter of interest, with the hope that others interested in the physiology and diseases of the gastro-intestinal tract may investigate the subject more completely. conditions of other abdominal organs, though it was not his experience to notice this frequency of gastric hyperacidity.

Paterson,[2] of London, only a few months ago, expressed his surprise at the frequency of gastric symptoms and the change in gastric secretions caused by appendicitis. In his opinion, the many symptoms of gastric ulcer and even gastric hemorrhage were found at times, by study as well as at operation, to be the sequel of appendicitis. In a few of his cases there was a normal acidity, in about 30 per cent. a hypo-acidity, and in the remaining a marked hyperchlorhydria. He says that "a combination of marked symptoms of gastric ulcer with a negative gastric analysis is suggestive of chronic appendicular disease," and that "in recent years it is becoming gradually recognized that hematemesis, accompanied by pain and vomiting, is not pathognomonic of gastric ulcer." His statement that a gastro-enter-whic[illegible]tomy will not remove a diseased appendix is strikingly tient wi[illegible]nt. While my experience is not exactly parallel has been perfo[illegible]Paterson, since mine shows appendicitis stomach will be relieved[illegible]itive change in gastric secretion

Dr. James T. Pilcher, Brooklyn: After a [illegible] yet 7,000 gastric analyses I wish to confirm Dr. Lichty's observations as regards the tendency to increased acidity of the gastric juice in cases in which there is gall-bladder involvement. However, as he so well pointed out, the other extreme is frequently encountered. While acknowledging the tendency to an increase of the hydrochloric acid content of the gastric juice in the majority of the cases of gall-bladder involvement in any of its many phases, I wish also to call attention to the fact that the other extreme may also be reached; in proof of this fact I will mention thirty-two cases of gall-bladder involvement and fifteen cases of combined gall-bladder and pancreatic involvement in which there was present, at the time of operation, a condition of achlorhydria hemorrhagica gastrica. Appreciating this, is is obvious that the conclusion that in all cases of gall-bladder involvement there is an increase in the acidity of the stomach would be erroneous in the large majority of the instances, although it obtains, as has been noticed, in some 300 cases which I have had the opportunity of examining.

I wish further to congratulate Dr. Lichty on emphasizing so strongly and expounding so clearly the fact that in cases of so-called *hyperchlorhydria we have not to do essentially* with the stomach, but should seek the etiologic factor which is giving rise to reflex gastric symptoms. The question is certainly a pertinent one. Is there any such a condition as hyperchlorhydria *per se?* The indications certainly point against it and it will only be through such experiments as have been carried on by Dr. Lichty that we can come to any definite conclusions. The work so far accomplished I am sure is more than indicative that many of the dictums laid down so precisely in the text-books on the subject are in some respects fallacious and will shortly require a complete revision.

Dr. A. L. Benedict, Buffalo, N. Y.: The stomach is, to a large degree, an indicator of disease of other organs. For instance, in 100 serial "stomach cases" I found that 80 patients were either entirely normal so far as gastric secretion, etc., were concerned or, at most, showed only trivial gastric disturbances. The underlying condition was chronic colitis, typhlitis or even localized inflammation of the appendix, gall-stones, etc. Thus, we may well expect reflex variation in the condition of the stomach contents. Still, in actual practice, following a uniform technic, it is surprising to note that the analyses repeated in any given case, almost always give consistent results. Several years ago, in the American Gastro-Enterological Association, several cases of hyperchlorhydria due to gall-stones were reported. My experience is that gall-stones frequently give a typical clinical picture of hyperchlorhydria, more typical in fact than most cases of genuine hyperchlorhydria, but that on actual analysis, the stomach contents are of very low acidity. Do not understand me, however, as deny-investigation of this subject from an experimental basis. Experiments on a number of dogs were begun two years ago and have been continued constantly since, with some very satisfactory and surprising results. The method of experimentation, briefly described, was as follows:

A number of healthy dogs were secured and a study was made of their gastric secretions. At definite intervals of two or three days the dogs were not fed until noon; then a meal of about 8 ounces of water, containing bread sufficient in quantity to make a gruel, was inserted into the stomach with a bulb and a stomach-tube. Thirty minutes later, this meal was removed and analyzed. We soon found that, if the bread and water remained in the stomach much longer than thirty minutes, the stomach was empty and the secretions and acids were low. In other words, the gastric secretions in dogs supplied with practically the Ewald meal were at the highest about thirty minutes after feeding. Aftgrees dozen or more test meals were given to each do nereas, if fairly accurate average estimation could b00 c.c. ingested, *gastric secretion, these dogs* were and the 25 *degree* standomy. At the first [illegible] basis for the diagnosis of hyperchlorhydria.

Now as to the exaggeration of the reading: using dimethyl-amido-azobenzol as an indicator, the end-point for free hydro*chloric acid is at the transition from a* distinct cherry red to a color almost exactly like that called cerise. We would naturally suppose that cherry-red and cerise meant the same tint but they do not. Beyond this end-point, the further addition of alkali produces changes, through orange to a straw yellow, for somewhere about 10 or even 15 degrees. One can readily see that a man who titrates to the final change, in estimating his free hydrochloric acid and perhaps overruns, at that, and who has started with the assumption that anything beyond 20, or perhaps 15 degrees of free hydrochloric acidity, is an excess, will find hyperchlorhydria, not only in normal cases, but in those in which there is a moderate hypochlorhydria—hence, a lot of nonsense about hyperchlorhydria associated with organic fermentation.

DR. G. C. SMITH, Boston: Ewald, several years ago when lecturing to students who came to him from all over the world to study diseases of the stomach, made the statement that 98 per cent. of all diseases with symptoms referable to the stomach originate from outside the stomach.

DR. GUSTAV BAAR, Portland, Ore.: What do we want to know when we see these cases? Shall we, as internists, attempt to cure these patients, or shall we turn them over to the surgeon? What are the additional signs and symptoms we can have besides hyperacidity which will enable us to determine whether we are dealing with some gastric trouble or with some extragastric trouble—appendicitis, perigastritis, etc.? In an examination of 10,000 urines, routine tests were made for indican and in nearly all hyperacidity cases caused by extragastric disturbances it was found constantly present. The constant presence of excessive indican in the urine means some anatomic disturbance of the gastrointestinal wall and calls for surgery.

DR. JOHN A. LICHTY, Pittsburg, Pa.: I have noticed in my clinical experience that many patients have consulted me for disturbances of the stomach when, in truth, the trouble was elsewhere. Many of them had hyperacidity and often there was a high *percentage* of free *hydrochloric acid.* They had also the typical symptoms of hyperchlorhydria. Many had been treated previously from time to time as "nervous dyspeptics." Three or four years ago, when at Leeds, I had an opportunity of referring to these cases in conversation with Mr. Moynihan, who impressed on me the fact that these patients were probably suffering from duodenal ulcer and might at any time have perforation. When I returned to my work, I continued my observations, but did not see a single instance of perforating duodenal ulcer. I did, however, find every now and then one of these patients with an attack of acute appendicitis from one day to the next. The variation was so great and constant that the physicians who made all the analyses could not overlook or explain it, until they found that, by some misunderstanding of the man who fed the dogs, the animals were given food after the removal of the test meal only every second day. They were then very hungry and ate much. The day following such a full meal the acids were generally high, but the second day thereafter, without any food for forty-eight hours, they were just as constantly low. At another time we secured several new dogs, on which gastric analyses were impossible or of little value, except for one point, the influence of excitement on the secretion. While foreign body intro-
dogs usually took the stomach ly showed an increased acidity
out any difficulty gastric motility. These results are in accord
stubbornly per which has just been read.

these DR. M. J. LICHTY, Cleveland, Ohio: It has been noticed for at some time that frequently gastric disturbances are present clinically, when the real trouble has been in other organs; just why this is so does not seem entirely clear to us at present. We frequently see high acidity of the gastric juice when there are gall-stones; and the high acidity disappears on the removal of these gall-stones. I have in mind an individual who had gall-stones and with this condition a high acidity, but when the gall-stones were removed the man became perfectly well. I am glad that Dr. Pilcher has called attention to the terms hyperacidity and hypersecretion. I did not mean to use them synonymously in the paper. Of course the terms signify different conditions, and these two conditions should be studied more both clinically and experimentally.

The question has been asked, What shall we do with these cases of disturbed secretions? We certainly should not subject all these patients to operation at once, though when these rather obscure cases do not improve under systematic treatment, they should require further study and operation may be necessitated. A patient recently referred to me on account of stomach trouble had no symptoms whatever except vomiting which had existed for weeks. At my first examination, I found some tenderness over McBurney's point and was rather confident that there was an unrecognized appendicitis. Operation proved it so and removed the symptoms.

I recall another patient who had gastric symptoms, but in whom I noticed, after repeated examinations, an occasional slight tenderness over the region of the appendix. This patient has been treated some years before for gastro-intestinal trouble by a physician whose practice is now confined to surgery. The same man was called in consultation and hesitated to confirm the diagnosis of chronic appendicitis. At last he approved of operation; and when he operated he could hardly find the little appendix, half obliterated and buried with many dense adhesions; but while removing it with great difficulty he remarked: "Here was likely the trouble when I treated this patient eleven years ago for dyspepsia."

Cholera Germs in Food.—P. Pospelow reports the results of extensive research in this line in the Russian *Wojenno Journal,* April, 1910, stating that the cholera vibrio is liable to persist unmodified in food, as it does not seem to be affected by the composition of the food or symbiosis with other micro-organisms or by changes in temperature. It is, however, extremely sensitive to the drying out of the medium and to the action of acids. It degenerates in acid and salted foods. It proliferates in solid and fluid media rich in organic elements, but degenerates in water free from organic elements. Dilution of wine and of contaminated water kills the cholera germs in from ten to fifteen minutes. They also die off in beer, but not so rapidly; this destructive action depends on the acid content and the content in acid salts rather than on the alcohol content, as the germs survive for five hours and over in diluted whiskey (*Kornbranntwein*). Pospelow's article was summarized in the *St. Petersb. med. Wchnschr.*, Oct. 8, 1910.

From the analyses made on dogs subjected to operations, we were able then to draw two other conclusions. First, it was noticeable that dogs showing depression or shock following operation had a very uniform lowering of the gastric acidity. The acidity was also lowered when there were adhesions around the stomach, whether binding it to gall-bladder alone, or to the gall-bladder and bowels and abdominal wall. Second, it was noticed that those dogs which [illegible] poliomyelitis acuta, not only [illegible] and which were [illegible] profession, but by laymen as well. Many new facts regarding the pathology, and particularly the etiology, have appeared in medical articles in this time. Mention may be made of the brilliant work of Landsteiner and Popper[1] and Flexner and Lewis.[2] These and other workers have demonstrated the infectiousness of the disease, which is undoubtedly caused by some virus. Their writings have given us a number of new facts regarding the pathology, but nothing radically new in the treatment.

This article will deal only with the treatment of the prodromal and acute stages.

As yet, there is no specific treatment. Vaccine or antitoxin treatment is being vigorously sought by several laboratory workers at this time. Apparently some time may elapse before such treatment is discovered. Then, to follow such a discovery, a critical, practical experimental period must elapse before the new treatment becomes generally adopted.

An early diagnosis—one before the paralytic stage has resulted—is particularly to be desired. Two laboratory diagnostic means are now available which may be of great value in determining the presence of the disease before any serious or irreparable damage to the nerve cells of the anterior horn has occurred. The blood-count shows an early mild leukocytosis with a decided increase in the lymphocytes and a decrease in the polymorphonuclear leukocytes. Lumbar puncture has usually demonstrated a mild increase in lymphocytes of the cerebrospinal fluid. There have been some cases observed with no increased cells in the cerebrospinal fluid, but it is possible that at some stage of the disease they may have been increased.

In a number of cases in which I have been called in consultation, drugs have been used to excess, particularly purgatives. There is no objection to using laxatives moderately in most of the cases. Ergot has been employed, but I believe that it is contra-indicated. I can see no reason why a drug which contracts the smaller arteries should be given in a condition in which the blood-supply of nervous centers is already diminished by a too small caliber of the smaller vessels. The iodids have been given, but have no value during the acute stage. One of the most important therapeutic means is rest. It is possible that if absolute rest could be obtained for a few days before the paralysis is due to appear, many cases would abort without paralysis. It is possible that the comparatively high percentage of the paralyses of the lower extremities may be accounted for by the increased blood-supply required for the nervous centers in the lumbar enlargement containing the motor cells for the lower extremities.

I wish to express my thanks to Drs. Stoner and Rogoff, who have done the many analyses with great care and labor and accuracy, as well as to Dr. Hambleton who did all the surgical operations on the dogs.

ABSTRACT OF DISCUSSION

Dr. DeLancey Rochester, Buffalo, N. Y.: In a paper pre- Hexamine [illegible] before the Medical Society of the State of New these patients. A number of experiments were reported strated that this chemical can be recovered from all of the secretions and excretions of the body in a short time after its ingestion. Crowe, at the suggestion of Cushing, demonstrated experimentally on animals and man that formaldehyd is present in the cerebrospinal fluid thirty minutes after the administration of hexamethylenamin (urotropin).[3] It is probably better to give the drug in as large doses as is safe over a period of a few hours, and then discontinue it for about twenty-four hours. My method is to give from 0.12 to 0.24 gm. to a child 2 to 4 years of age, giving a dose every hour until three doses have been given. No more is then given until the following day at the same hour, when it is repeated in the same manner. This repetition may be employed as long as acute symptoms persist. Thus, we suddenly load the body with the chemical, and then allow a short period of rest. We might give 3 to 8 gm. of the drug to the adult during the daily three or four-hour period of its administration.

During the past two months I made a diagnosis of poliomyelitis acuta in five cases in the prodromal stage. The hexamethylenamin treatment, as outlined above, was given to all these patients and three made recoveries without any paralysis. One child, cared for under unfavorable circumstances, died; and another, whose case was of the *foudroyant* type, developed paralysis. Hexamethylenamin has also been given to a few children in families in which there was great fear that others might contract the disease.

Some of the patients suffer from much pain and hypersensitiveness. To these may be given some form of the salicylates, preferably sodium salicylate or acetylsalicylic acid (aspirin). I have found the latter more agreeable for children. I have obtained much relief in a few cases by applying a heavy cotton dressing to the involved extremities. Partial immobilization may have been a factor in the results obtained.

We now have sufficient evidence at hand, experimentally and clinically, to warrant instituting some kind of isolation and care to prevent the transmission of the virus. A few health boards now include poliomyelitis acuta among the diseases to be reported. The Kansas State Board of Health at a meeting in June, 1910, made a rule that all cases of poliomyelitis acuta must be reported to the proper health officers, and a sign bearing the words "Infantile Paralysis" posted on the house; and that all people not required to care for the patient be prohibited from entering the sick-chamber.

In private practice, I direct that the patient be kept alone in one room, and only those actually required for care and nursing be permitted to enter. Instructions are given to sterilize by boiling or chemicals all articles used by the patient and to disinfect secretions and excreta.

ing that there may be genuine hyperchlorhydria in gall-stone cases.

One more point: Many men speak of hyperchlorhydria as a common condition and one that can be diagnosed symptomatically. I do not believe that it can ever be positively diagnosed except by analysis. Furthermore, there is an unfortunate tendency both to exaggerate the degree of hydrochloric acidity and to accept a low standard of normal acidity. The hydrochloric acid of gastric juice is normally about 20 to 10,000, corresponding approximately to 50 degrees by N/10 alkali. For chyme, we may assume, approximatel[illegible] cent. dilution of [illegible] hydrocl[illegible]

[illegible] developed an extraordinary [illegible] and gives wide-spread metastasis. Work with it has brought out facts which bear largely on the general problem of tumor metastasis and tumor immunity.

The sarcoma has passed through six generations of inoculated fowls during the last thirteen months. It is of spindle-celled variety and has throughout remained true to type. In the degenerated portions true mucin may be found. The specificity which at first limited its successful transmission to fowls of the same pure-bred stock in which the growth arose has been to some extent overcome. It now grows in about 85 per cent. of these pure-bred fowls—light, barred Plymouth Rocks—and in an occasional individual that shows by its plumage the slight admixture of some darker strain; but it grows only in Plymouth Rocks. Retrogressions of the developed tumor are rare.

The increase in the malignancy of the sarcoma followed the use of young hosts. Prompt invasion and metastasis are now the rule. Grafts removed and examined three days after implantation are found vascularized, and the sarcoma cells have already pushed into the host's tissues well beyond the boundary of the introduced bit. A fragment 1 to 2 mm. in diameter, placed with a trochar in the breast muscle, may give rise in the course of a month to a mass measuring 8 by 4.8 by 4.2 cm. From clavicle to lower sternum the muscle fibers are almost completely replaced by tumor. The host rapidly emaciates, becomes cold, weak and somnolent and shortly dies.

Metastasis takes place through the blood-stream and much more rarely through the lymphatics. The lungs are often almost completely replaced by coalescing growths, and less frequently the liver and kidneys show nodules. The serous membranes may be penetrated and a wide-spread peritoneal dissemination follow. Intraperitoneal growths may cause intestinal occlusion, or may unite viscera that lie far apart into a common mass. In general the secondary tumors spare or affect the same organs as in mammals, the spleen, for example, enjoying an almost complete immunity as compared with the lungs, liver and kidneys. The reason for this freedom of the spleen from tumor metastasis is not apparent.

Metastases appear in the heart with great constancy, a feature not seen in mammals. Both sides of it are involved about equally often and the organ may be almost completely replaced by tumor tissue before the host dies. In such cases it is found greatly enlarged, pale, stiff and roughened by growths that have broken through on its surface. The pericardium is thickened with contact metastases.

Metastases develop best when the primary tumor grows slowly. When it grows rapidly the host dies before the secondary nodules have had time to reach a large size. In such animals great numbers of minute metastases are found, but apparently a sufficient interval

dicitis or an attack of gall-bladder or gall-duct trouble, and, at the operation, the pathology revealed, always showed that attacks must have occurred previously, the history of which I was unable to get, and that the whole train of symptoms must have been due to the lesion found. It occurred to me that probably hyperchlorhydria was an accompanying symptom of gall-bladder, or appendix affection. For this reason, I experimented on dogs to determine whether a foreign body in the gall-bladder or in the appendix or the adhesion produced mig[illegible] disturbance of gastric function

A study of grafts of the sarcoma [illegible] was used and intervals from susceptible fowls, and fowls with a[illegible] natural or acquired resistance, has shown that this resistance does not depend on the absence of a supporting and vascularizing reaction for the graft—a phenomenon held by many to be of primary importance in tumor immunity. It is true that an absence of such a supporting reaction is not infrequently responsible for the death of grafts in the resistant animal, especially when they have been placed in a site where connective tissue is nearly wanting; but in by far the greater number of cases the graft undergoes vascularization. Its success is nevertheless of short duration. In the first few days after inoculation, while it is growing and seems healthy, there occurs a rapid accumulation of small round cells, (lymphocytes) first about the near-by blood-vessels, then extending around and into the tumor graft. A week from the time of its implantation this is so inclosed by small round cells (and to a much less degree by large mononuclears, plasma-cells and fibroblasts) that on a casual glance one would think it part of a lymph-gland. At this time it is, as a rule, rapidly degenerating, although well vascularized. Exceptionally it does not die but continues to proliferate, despite the indications of resistance by the host, and eventually establishes itself. In susceptible fowls one finds at the edges of the growing tumor a less marked reaction of the sort described. There are traces of it about the original neoplasm. It is not called forth by material killed by heat (60 C. for thirty-five minutes) or repeated freezing and thawing.

Immunity in the case of this chicken sarcoma does not then depend primarily on the absence from the host tissues of a supporting reaction and vascularization for the graft. There are indications in the literature that this phenomenon, so obvious in rats and mice, is here also secondary to less understood processes. Burgess[2] examining grafts removed from mice racially insusceptible to the tumor inoculated, has found them vascularized and growing for a short period, then surrounded by granulation tissue and degenerating. Da Fano[3] after a careful histologic study of tumor grafts in mice, and of the sparse cellular reaction about them, has come to the conclusion that lymphocytes are in some way connected with tumor immunity. About the growing tumors of man lymphocytes are not infrequently seen in considerable numbers.

The conclusion seems justified that resistance to tumor growth can no longer be considered to depend *primarily* on a failure of the host to provide a stroma and vascularization for the neoplastic cells. Both may be provided by the resistant host, and yet the tumor dies. Whether the lymphocytes which accumulate about it, or, some factor unknown, is responsible for this result, has yet to be investigated.

The chicken sarcoma has recently been cultivated *in vitro* by Drs. Carrel and Burrows.[4]

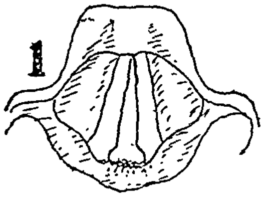
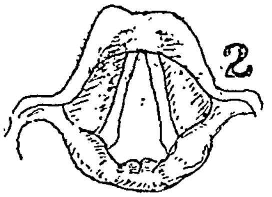
THE DIAGNOSIS AND TREATMENT OF THE EARLIER CHANGES IN THE LARYNX IN PULMONARY TUBERCULOSIS*

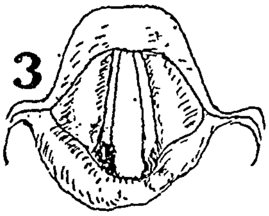
C. L. MINOR, M.D.
ASHEVILLE, N. C.

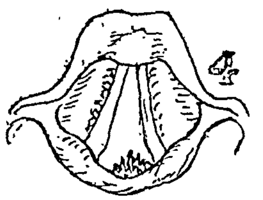
There is no more encouraging fact in the development of modern medicine than the interest that is being taken in the early diagnosis and the rational treatment of pulmonary tuberculosis. The medical profession must not be satisfied, however, with what has been accomplished, for satisfaction with one's own achievements rings the knell of all further progress; rather, physicians should keep their minds open to discern where the present practice is imperfect and be ready to correct flaws as soon as they are discovered.

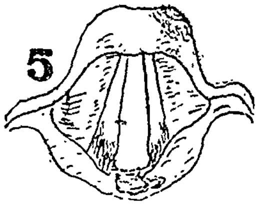
An important defect in the early diagnosis of tuberculosis is the fact that few physicians in the examination of such patients pay any attention to the condition of the larynx or are capable of making the necessary examination to determine the condition of this organ.











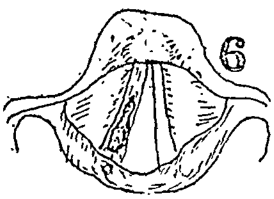


Fig. 1.—Gray wrinkling of posterior commissure, which is not diagnostic, but is suspicious if tuberculosis exists in the lungs. *It can be found in many cases of chronic laryngitis.*

Fig. 2.—Typical table-like elevation in posterior commissure, with central longitudinal groove. The mucous membrane over it is usually unduly red, but at times is edematous and yellowish. This is the [illegible] of Schroetter.

[illegible] f the right arytenoid region and reddening of [illegible] of the right and left cords, this last being very typical and often showing a small white ulcer at the processus vocalis. *Right false cord is slightly redundant.*

Fig. 4.—Granulations arising from an ulcer in the posterior commissure and hiding the ulcer.

Fig. 5.—Superficial dirty ulcer of posterior commissure invading its upper surface and thereby causing severe dysphagia. Thickening and ulceration of epiglottis. Thickening and redness of posterior ends of cords which are invaded by ulcer of posterior commissure.

Fig. 6.—Superficial ulcer of upper surface of right cord.

No examination of a tuberculous patient can be called satisfactory or thorough in which a laryngeal examination has not been made, and the value of this examination to the patient and to the physician in charge will be greatly increased if the latter has taken time to master the technic of laryngoscopy so that he can see the condition of things for himself and not through another's eyes, for no other man's report of what he has seen or found can begin to equal in its effect on the mind the results of one's own observations. Therefore, it is always greatly to be regretted when the physician has to depend on the report of another as to existing conditions in a patient, and while in view of the enormous growth of modern medicine this is necessary in many cases, notably as regards laboratory work, which no busy practitioner, however well-trained, has time to do for himself, laryngoscopy is so easily learned and so easy and quick of application when once learned that no physician who wishes to be thorough need say that he cannot master it or that he has not time to apply it.

Further, a review of the literature of the subject shows that the laryngeal conditions usually recognized and spoken of are not those early and curable changes which can be discovered only by the use of the laryngoscope, but rather relatively advanced alterations such as turbaned epiglottes, pear-shaped arytenoids, extensive ulcerations of cords or commissure or epiglottis, which produce symptoms. This explains why the profession looks on laryngeal tuberculosis as a *noli me tangere* and considers a diagnosis of such trouble as tantamount to a death sentence. If the physician would take the trouble to master laryngeal technic, not necessarily so thoroughly as to prepare himself to do endolaryngeal operations but so as to enable him easily and thoroughly to look at the larynges of patients and familiarize himself with the early changes which antedate the conditions I have noted, he would find many tuberculous throats which he had not suspected, and also that a much larger percentage of such patients can be cured than he had hitherto supposed. While I would not, of course, wish to be understood as saying that laryngoscopy is not a matter of skill, I am ready to assert that it is not an extremely difficult matter to learn to see the larynx clearly, and after a man has learned to see clearly he only needs brains and opportunity to learn to diagnose these conditions early.

If it becomes an accepted view that a laryngeal examination is a routine and essential part in every physical examination, it will not be long before the physicians learn that the prognosis in laryngeal tuberculosis is not what they have thought it to be, and it is to encourage such an attitude that this article is written.

The symptoms of early laryngeal tuberculosis are limited in number and not so valuable as the signs. The earliest is usually a mere weakening of the voice which may exist for a long time before any hoarseness appears; and here let me note that while hoarseness is a prominent and often an early symptom it is by no means always present, and that the case can advance considerably before it appears; sometimes, however, it is surprising how well the voice is retained despite extensive trouble. Next to a weak voice I would note a sense of dryness in the throat with which is soon associated an *insufferable localized tickling, scratching or pricking as* though a hair had been swallowed. In my experience, pain on swallowing is not usually an early symptom, although a consciousness of the larynx at such times, as if a lump were in the throat, comes soon.

The subjective symptoms, however, are relatively unimportant compared to the great importance of the objective signs. While it has been generally taught that pallor of the mucous membrane is the earliest change in this disease, recently several voices have been raised against this view, notably Lockard's in his recent book. I have not found this often an early sign, and I believe that catarrh with hyperemia is usually the first manifestation of beginning trouble, though, of course, this is not in itself at all diagnostic. Those who treat pulmonary tuberculosis have, I believe, an earlier opportunity of seeing the beginning lesions in the larynx than the laryngologist has, save in a health resort, for when a patient consults a specialist in a city it is usually for pronounced and troublesome symptoms, whereas, since pulmonary trouble usually greatly antedates laryngeal lesions, by systematically watching the throats of his pulmonary patients the physician often has the chance to see the very beginnings of the trouble.

---

* Read before the National Association for the Study and Prevention of Tuberculosis, in Washington, D. C., May, 1910.

It is only when the catarrh referred to begins to localize itself and becomes unilateral and persistent that it becomes really suspicious; for it must be recalled that every pulmonary patient is unduly subject to ordinary laryngeal catarrh. An obstinate patchy catarrh localized, however, to one cord or to one arytenoid is highly suspicious, though not positively diagnostic, but such a localized condition occurring in a patient in whose lungs we know there is a tuberculous deposit, can safely be considered as tuberculous and the trouble is frequently on the same side as the lesion in the lung.

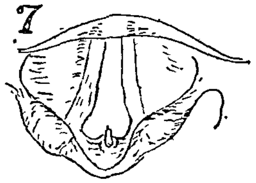
Next to this I would note as highly significant a grayish wrinkling of the posterior commissure (Fig. 1). This I believe to be the commonest early finding, but since it can be simulated by a chronic catarrh, such as is often seen in public speakers, it will not do to base a diagnosis on this alone. The earliest change which has real diagnostic significance is, in my experience, a tablelike elevation of the mucous membrane in the posterior commissure (Fig. 2). This generally occupies the center of the commissure, in which case it shows a vertical furrow or depression down its center, dividing it into two symmetrical halves; but it is frequently unsymmetrical and situated to one or the other side of the center. The color is generally grayish-pink, though at times it may be congested.

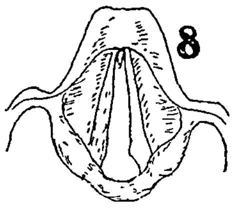
Such an elevation in this location I believe to be pathognomonic, and in this view have the support of so able an authority as Schnitzler. Such elevations tend to break down into shallow ulcers, though they may remain intact for a long time, but when ulceration does occur their tendency to fill up with exuberant pointed granulations (Fig. 4) often conceals their nature and causes them to pass for tuberculomata. Such infiltrations under suitable treatment may slowly but entirely disappear.

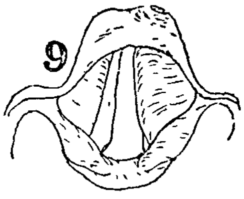
Next to the posterior commissure as a site of early changes is the vocal process, the posterior insertion of one cord, or the body of the cord itself. In the first case the cord at its posterior end is red, thickened and beefy (Figs. 3 and 5) and a small white ulcer tends finally to form and takes on a triangular shape, its apex forward at the vocal process, its base posteriorly at the commissure. When the cord itself is invoked it is at first congested and slightly thickened (Fig. 8), and finally becomes fleshy and spindle-shaped (Fig. 10), a very typical condition in this disease, while if it begins to ulcerate the area where the ulcer is to form looks pale and thickened.

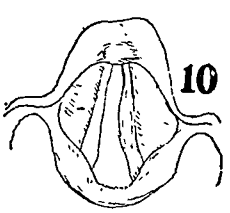
Ulcers of the cord, instead of being localized in one spot (Fig. 12) may be scattered along the edge, producing the characteristic nibbled-out appearance (Fig. 11). Tuberculous ulcers tend to be shallow, and of indefinite outline, to run together and to be multiple, and, if on the cord, are usually in its posterior one-third (Fig. 6). A longitudinal ulcer along the free edge of the cord and giving the impression that the cord is double or split, is a common but not an early change. Quite an early change is the thickening and yellowing of the false cords or ventricular bands which partially or totally hide the underlying cord and are very effective in producing hoarseness (Fig. 9). The upper surface often shows erosions or shallow greyish-yellow ulcers, but not usually early in the course of the case.

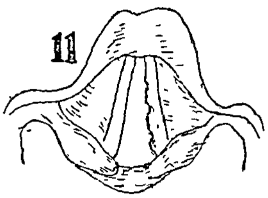
Very early in the disease we find some involvement of the arytenoid region, either localized congestions or anteroposterior thickenings (Fig. 3). In my experience the cartilage of Wrisberg shows reddening sooner than that of Santorini. Another typical change in the posterior commissure is the formation of pointed or round tuberculomata which, though they can resemble soft granulations, are surprisingly hard and firm to the touch and may persist unaltered for years (Fig. 3). Thickening of the ary-epiglottic folds is a more advanced change, but when present is pathognomonic. Likewise changes in the epiglottis do not occur early, though sometimes they can be foreshadowed for a long time as areas of slight thickening and reddening of its edge or posterior surface (Figs. 5 and 9).











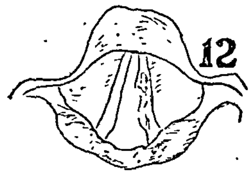


Fig. 7.—Hornlike growth in posterior commissure with reddening of posterior half of right cord.

Fig. 8.—Small growth protruding between cords in anterior commissure. Right cord is irregularly thickened and reddened.

Fig. 9.—Great thickening of left false cord which overlaps and hides the true cord. Arytenoids and posterior commissure somewhat thickened. Swelling and beginning ulcer on epiglottis.

Fig. 10.—Spindle-shaped thickening with reddening of the left cord. Reddening of petiolus of epiglottis.

Fig. 11.—Small ulcers on free border of left cord, giving characteristic nibbled-out appearance.

Fig. 12.—Spindle-shaped thickening and ulceration of left cord.

I might also mention as an early change, though a rare one, the protrusion of a small teat of red granulation beneath the anterior commissure (Fig. 8); when seen its diagnostic value is great.

Such are, I believe, the earliest changes to be found in the larynx in tuberculosis, and if the physician will examine every patient with pulmonary tuberculosis for laryngeal changes he will be surprised to find how large

Following the vaccination, usually within six to eight hours, a hyperemic area, about the size of the palm of the hand, develops at the point of inoculation. Rarely, this hyperemia is attended with some brawny induration, with enlargement and tenderness of the axillary lymph-nodes, but suppuration never occurs. The local reaction may or may not be accompanied by systemic disturbances. When present, systemic reaction may be manifested by slight pyrexia and malaise, in mild cases; and rheumatoid pains, nausea, rigors, considerable pyrexia, profuse perspiration, herpes, or nervous disturbances in the severer reactions. I have seen one case of hysteria follow inoculation. The symptoms subside within forty-eight hours in the severest reactions—usually within twenty-four hours—and the records of over 31,000 inoculations show no serious untoward results.

Laboratory researches demonstrate that the agglutinin, opsonin, and bacteriolysin of the blood-serum are increased by antityphoid vaccination and that the increase is greater and more persistent than that conferred by an attack of typhoid fever. Typhoid outbreaks, in commands in which there were both inoculated and uninoculated individuals, have demonstrated, practically, what we should have expected from the laboratory evidence; and a recent typhoid situation at Washington Barracks, D. C., illustrates the efficacy of antityphoid vaccination so conclusively that it is deemed worthy of record.

On June 14, ten days prior to leaving Washington Barracks for the Gettysburg maneuvers, 92 members of Company A, First Battalion of Engineers, received the first antityphoid inoculation. On July 6, 52 of the above men received the second inoculation, and on July 16, 51 of these received the third inoculation. Of the remaining 26 men of the command, a few refused vaccination and others were on detached duty or temporarily absent when the first inoculation was given.

Two of the 26 uninoculated men gave a history of having had typhoid fever, and by virtue of that fact may be considered immune. This leaves 24 men, of the total strength of 118 men, who had not acquired an immunity to typhoid fever by either preventive inoculation or a previous attack of the disease.

On August 11, five days after the troops returned from Gettysburg, two of the uninoculated men developed typhoid fever, and, between August 20 and 23, four secondary cases occurred—also among the uninoculated. Not a single case occurred among those who had received the preventive inoculations, while 25 per cent. of the non-immune, living under exactly the same conditions, succumbed to infection.

Such figures as these are eloquent in calling attention to the practical application of antityphoid vaccine in the prevention of typhoid fever. With no serious results following over 31,000 inoculations in the army, we may say with certainty that the procedure is safe, and statistics available at this time show that the immunity conferred by vaccination lasts for at least three years.

About one-seventh of the personnel of the regular army have now been vaccinated, and a regulation requiring the vaccination of all recruits and all those presenting themselves for re-enlistment would result, within three years, in a regular army practically immune to typhoid fever. Furthermore, in the event of hostilities, should the vaccination of the reserve army—militia and volunteers—be made compulsory before mobilization, it is reasonable to prophesy that the medical history of our land forces in past wars, as regards the incidence of typhoid fever, would not repeat itself.

Therapeutics

INDIGESTION

This condition, sometimes called the American disease, is certainly not growing less frequent, and its results are becoming more serious because the general system does not seem to withstand irritants so well as it did even 25 or 50 years ago. The human being of to-day with his higher civilization is subjected to a series of unceasing irritations—irritations to almost every sense and every part of the nervous system—which tend to cause nervous tension and increased circulatory-tension, and the results are arteriosclerosis and chronic nephritis. These two end-results are further caused and precipitated by the irritants that are absorbed from the alimentary tract. Normal digestion offers no such irritants; abnormal digestion, or indigestion, offers irritants which are more or less absorbed, which are for a long time tolerated, which are insidious in their results, and may for years cause no organic disturbances. There are, however, early and persistent symptoms of indigestion which the patient can recognize. Unfortunately, however, an adult for months may take no particular notice of disturbances that do not cause him distress.

There are so many causes of maldigestion that they could hardly all be enumerated in any one list. We may start out with the presumption that there is no organic trouble causing indigestion as a secondary condition. The first determination to be made when a patient complains of indigestion is that there is no circulatory or kidney excuse for the condition. The next determination should be as to whether the patient has simple indigestion *or* has *an inflammation of some part of the* digestive tract, and it is generally possible to decide whether simple dyspepsia or actual gastritis is present, or whether simple intestinal indigestion or an inflammation of some part of the intestinal canal is present. If it is determined that there is an inflammation of the mucous membrane, *i. e.*, gastritis, duodenitis, enteritis, or colitis, the treatment would be different than when there is simple disturbed digestion.

An acute inflammatory condition is readily recognized, and consequently correctly treated. A chronic inflammatory condition is not so readily determined, consequently more scientific examinations are necessary. The clinical history, signs, and an ordinary physical examination are not sufficient. The feces must be properly examined after a known diet.

Pediatricians for a long time have advised this method of determining the correct food for a given infant, and what he can digest. A few clinicians have long urged a more careful study of the stools of adults when there are disturbances of digestion, but the majority of practitioners take no notice of this aid in making a diagnosis and coming to a decision as to the proper food and proper treatment. It may readily be determined by such an examination of the feces which foods are best digested; whether the trouble is probably in the stomach or in the intestines; whether or not there is a deficiency of bile; whether or not there is an insufficient amount of pancreatic juice; whether there is a probable insufficient secretion from the intestinal walls and glands or not; whether peristalsis is delayed and the motility of the bowels sluggish; whether there is blood extravasated from some portion of the stomach and intestine; whether there is an abnormal amount of mucus; and last whether or not there is pus. Abnormality in the feces will give indications as to the etiology of the condition and the best line of treatment. If it seems probable that the a number show some alteration from the normal, the more conservative estimates placing this at 30 per cent. of all cases.

Regarding the therapeutics of this stage, first and foremost I would place absolute rest to the voice, though there is nothing so difficult as to induce a patient to stop talking absolutely, and to use only writing as a means of communication. Even whispering should not be allowed, as it is by no means compatible with rest of the larynx. Next is the avoidance of all irritants, notably smoke, dust and furnace-dried air, smoking being, I believe, absolutely harmful in these cases. Third is cleanliness, which I attend to by having the patient spray the larynx, and not the mouth, with an alkaline solution, using a proper long-stemmed atomizer with a tip at right angles and pointing downward. Fourth is the use of astringents. When there is much congestion or soreness I find an astringent spray of alumnol 2 per cent. very useful, while if the throat is not too congested, one of the common mentholated oily sprays will be comforting. I have been able to teach my patients to spray their own throats very satisfactorily, and the relief to the symptoms and the improvement in signs are marked.

However, the drug which I have come to rely on more than any other to cure these cases is iodoform; not the ordinary amorphous form, but the fine crystalline form which is not usually found in drug stores. This I have the patient insufflate morning and night from a proper apparatus which, like the atomizer, must be long enough to reach over the top of the larynx and must have a tip which will blow the powder directly down into that organ. It is surprising what excellent results can be obtained in non-ulcerated or slightly ulcerated cases by the systematic and faithful use of this measure and how infiltrations can be absorbed or made inactive.

Since in early cases there is rarely dysphagia, the use of local anesthetics is not usually called for; when needed I have usually found insufflations of orthoform before meals very satisfactory, or when this is not sufficient solutions of acetate of morphin, 5 gr. to the ounce, taking care not to use it too freely.

Before closing, let me warn the physician who has not had careful training in making endolaryngeal applications with the cotton-tipped laryngeal sound, against resorting to them in the treatment of ulcerations. Of course for infiltrations they are of no use and would only do harm. Lactic acid so applied in moderately advanced cases is a valuable remedy, and I have seen many ulcers heal under its use, but unless one is familiar with the use of the laryngeal sound, it is easy to do great harm with it, and it should, therefore, only be used by the expert.

Finally, I am sure that if physicians will take the time and trouble thus to examine the throats of their tuberculous patients, they will find that the results fully justify the time and effort needed, and that through discovering the lesions early and treating them while yet they may be cured, they will come to take a less hopeless view of the prognosis of these cases than has hitherto been the case.

ANTITYPHOID VACCINATION

AN INSTANCE ILLUSTRATING ITS EFFICACY*

GEORGE B. FOSTER, JR., M.D.
First Lieutenant, Medical Corps, U. S. Army
WASHINGTON, D. C.

Typhoid fever has been the scourge of armies in campaign in every war of recent years. Our own army was crippled to a greater extent by this disease, during the Spanish-American War, than by all the other conditions combined that tend to decrease the morale and fighting efficiency of an army. During that short campaign there occurred 20,738 cases of typhoid fever among 107,973 men, with 1,580 deaths. In the Boer War the English had 31,000 cases, with 5,877 deaths; and during the Franco-Prussian War the Germans had 73,396 cases, with 8,789 deaths. Statistics as to the incidence of this disease in the Russo-Japanese War have never been published.

Sanitary campaigns have been waged against typhoid fever in our military service and civil communities with very material results; but, after exhausting every possible sanitary expedient, sporadic outbreaks continue to occur. The board of medical officers who investigated the origin and spread of typhoid fever in the U. S. military camps during the Spanish War, prophesied that, "with typhoid fever as widely disseminated as it is in this country, the chances are that if a regiment of 1,300 men should be assembled in any section and kept in a camp the sanitary conditions of which were perfect, one or more cases of typhoid fever would develop." This prophecy has been borne out, time and again, during the summer maneuvers of the army since that time.

Laboratory investigations have shown that 3 per cent. of those recovering from typhoid fever continue, indefinitely, to excrete typhoid bacilli capable of infecting others; and it must be conceded that, with these "carriers" acting as foci for the dissemination of the disease, "residual" typhoid will remain, despite the greatest sanitary vigilance. It is obvious, then, that some adjunct to the usual sanitary measures is necessary in an attempt to reduce still further the typhoid morbidity. Antityphoid vaccination seems to meet this necessity.

Protective inoculation against typhoid fever was instituted in the U. S. Army, in March, 1909; and over 12,000 persons have been inoculated up to this time (Oct. 1, 1910).

The vaccine is prepared at the U. S. Army Medical School, Washington, D. C. A non-virulent strain of the typhoid bacillus is grown on agar, slanted in flasks, for eighteen hours. The growth is then emulsified in sterile salt solution. The emulsion is standardized so as to contain 1,000,000,000 bacilli to the cubic centimeter, and sterilized at a uniform temperature of 56 C. for one hour. To insure its sterility, the vaccine is tested out aerobically and anaerobically; 0.25 per cent. of tricresol is added as a preservative, and it is put up in sterile glass ampoules (1 c.c. and 5 c.c.), in which form it is distributed for use. As a final test, before issue, the vaccine is proved innocuous by injection into guinea-pigs and mice.

A complete vaccination consists of three inoculations at ten-day intervals. The vaccine is administered hypodermatically, giving 0.5 c.c. (500,000,000 bacteria) as the initial dose, and a full cubic centimeter (1,000,000,000 bacteria) at each subsequent inoculation.

ANTITYPHOID VACCINATION

AN INSTANCE ILLUSTRATING ITS EFFICACY*

GEORGE B. FOSTER, JR., M.D.
First Lieutenant, Medical Corps, U. S. Army
WASHINGTON, D. C.

Typhoid fever has been the scourge of armies in campaign in every war of recent years. Our own army was crippled to a greater extent by this disease, during the Spanish-American War, than by all the other conditions combined that tend to decrease the morale and fighting efficiency of an army. During that short campaign there occurred 20,738 cases of typhoid fever among 107,973 men, with 1,580 deaths. In the Boer War the English had 31,000 cases, with 5,877 deaths; and during the Franco-Prussian War the Germans had 73,396 cases, with 8,789 deaths. Statistics as to the incidence of this disease in the Russo-Japanese War have never been published.

Sanitary campaigns have been waged against typhoid fever in our military service and civil communities with very material results; but, after exhausting every possible sanitary expedient, sporadic outbreaks continue to occur. The board of medical officers who investigated the origin and spread of typhoid fever in the U. S. military camps during the Spanish War, prophesied that, "with typhoid fever as widely disseminated as it is in this country, the chances are that if a regiment of 1,300 men should be assembled in any section and kept in a camp the sanitary conditions of which were perfect, one or more cases of typhoid fever would develop." This prophecy has been borne out, time and again, during the summer maneuvers of the army since that time.

Laboratory investigations have shown that 3 per cent. of those recovering from typhoid fever continue, indefinitely, to excrete typhoid bacilli capable of infecting others; and it must be conceded that, with these "carriers" acting as foci for the dissemination of the disease, "residual" typhoid will remain, despite the greatest sanitary vigilance. It is obvious, then, that some adjunct to the usual sanitary measures is necessary in an attempt to reduce still further the typhoid morbidity. Antityphoid vaccination seems to meet this necessity.

Protective inoculation against typhoid fever was instituted in the U. S. Army, in March, 1909; and over 12,000 persons have been inoculated up to this time (Oct. 1, 1910).

The vaccine is prepared at the U. S. Army Medical School, Washington, D. C. A non-virulent strain of the typhoid bacillus is grown on agar, slanted in flasks, for eighteen hours. The growth is then emulsified in sterile salt solution. The emulsion is standardized so as to contain 1,000,000,000 bacilli to the cubic centimeter, and sterilized at a uniform temperature of 56 C. for one hour. To insure its sterility, the vaccine is tested out aerobically and anaerobically; 0.25 per cent. of tricresol is added as a preservative, and it is put up in sterile glass ampoules (1 c.c. and 5 c.c.), in which form it is distributed for use. As a final test, before issue, the vaccine is proved innocuous by injection into guinea-pigs and mice.

A complete vaccination consists of three inoculations at ten-day intervals. The vaccine is administered hypodermatically, giving 0.5 c.c. (500,000,000 bacteria) as the initial dose, and a full cubic centimeter (1,000,000,000 bacteria) at each subsequent inoculation.

---

* Published with the permission of the Surgeon-General of the Army.

Following the vaccination, usually within six to eight hours, a hyperemic area, about the size of the palm of the hand, develops at the point of inoculation. Rarely, this hyperemia is attended with some brawny induration, with enlargement and tenderness of the axillary lymph-nodes, but suppuration never occurs. The local reaction may or may not be accompanied by systemic disturbances. When present, systemic reaction may be manifested by slight pyrexia and malaise, in mild cases; and rheumatoid pains, nausea, rigors, considerable pyrexia, profuse perspiration, herpes, or nervous disturbances in the severer reactions. I have seen one case of hysteria follow inoculation. The symptoms subside within forty-eight hours in the severest reactions—usually within twenty-four hours—and the records of over 31,000 inoculations show no serious untoward results.

Laboratory researches demonstrate that the agglutinin, opsonin, and bacteriolysin of the blood-serum are increased by antityphoid vaccination and that the increase is greater and more persistent than that conferred by an attack of typhoid fever. Typhoid outbreaks, in commands in which there were both inoculated and uninoculated individuals, have demonstrated, practically, what we should have expected from the laboratory evidence; and a recent typhoid situation at Washington Barracks, D. C., illustrates the efficacy of antityphoid vaccination so conclusively that it is deemed worthy of record.

On June 14, ten days prior to leaving Washington Barracks for the Gettysburg maneuvers, 92 members of Company A, First Battalion of Engineers, received the first antityphoid inoculation. On July 6, 52 of the above men received the second inoculation, and on July 16, 51 of these received the third inoculation. Of the remaining 26 men of the command, a few refused vaccination and others were on detached duty or temporarily absent when the first inoculation was given.

Two of the 26 uninoculated men gave a history of having had typhoid fever, and by virtue of that fact may be considered immune. This leaves 24 men, of the total strength of 118 men, who had not acquired an immunity to typhoid fever by either preventive inoculation or a previous attack of the disease.

On August 11, five days after the troops returned from Gettysburg, two of the uninoculated men developed typhoid fever, and, between August 20 and 23, four secondary cases occurred—also among the uninoculated. Not a single case occurred among those who had received the preventive inoculations, while 25 per cent. of the non-immune, living under exactly the same conditions, succumbed to infection.

Such figures as these are eloquent in calling attention to the practical application of antityphoid vaccine in the prevention of typhoid fever. With no serious results following over 31,000 inoculations in the army, we may say with certainty that the procedure is safe, and statistics available at this time show that the immunity conferred by vaccination lasts for at least three years.

About one-seventh of the personnel of the regular army have now been vaccinated, and a regulation requiring the vaccination of all recruits and all those presenting themselves for re-enlistment would result, within three years, in a regular army practically immune to typhoid fever. Furthermore, in the event of hostilities, should the vaccination of the reserve army—militia and volunteers—be made compulsory before mobilization, it is reasonable to prophesy that the medical history of our land forces in past wars, as regards the incidence of typhoid fever, would not repeat itself.

Therapeutics

INDIGESTION

This condition, sometimes called the American disease, is certainly not growing less frequent, and its results are becoming more serious because the general system does not seem to withstand irritants so well as it did even 25 or 50 years ago. The human being of to-day with his higher civilization is subjected to a series of unceasing irritations—irritations to almost every sense and every part of the nervous system—which tend to cause nervous tension and increased circulatory-tension, and the results are arteriosclerosis and chronic nephritis. These two end-results are further caused and precipitated by the irritants that are absorbed from the alimentary tract. Normal digestion offers no such irritants; abnormal digestion, or indigestion, offers irritants which are more or less absorbed, which are for a long time tolerated, which are insidious in their results, and may for years cause no organic disturbances. There are, however, early and persistent symptoms of indigestion which the patient can recognize. Unfortunately, however, an adult for months may take no particular notice of disturbances that do not cause him distress.

There are so many causes of maldigestion that they could hardly all be enumerated in any one list. We may start out with the presumption that there is no organic trouble causing indigestion as a secondary condition. The first determination to be made when a patient complains of indigestion is that there is no circulatory or kidney excuse for the condition. The next determination should be as to whether the patient has simple indigestion or has an inflammation of some part of the digestive tract, and it is generally possible to decide whether simple dyspepsia or actual gastritis is present, or whether simple intestinal indigestion or an inflammation of some part of the intestinal canal is present. If it is determined that there is an inflammation of the mucous membrane, *i. e.*, gastritis, duodenitis, enteritis, or colitis, the treatment would be different than when there is simple disturbed digestion.

An acute inflammatory condition is readily recognized, and consequently correctly treated. A chronic inflammatory condition is not so readily determined, consequently more scientific examinations are necessary. The clinical history, signs, and an ordinary physical examination are not sufficient. The feces must be properly examined after a known diet.

Pediatricians for a long time have advised this method of determining the correct food for a given infant, and what he can digest. A few clinicians have long urged a more careful study of the stools of adults when there are disturbances of digestion, but the majority of practitioners take no notice of this aid in making a diagnosis and coming to a decision as to the proper food and proper treatment. It may readily be determined by such an examination of the feces which foods are best digested; whether the trouble is probably in the stomach or in the intestines; whether or not there is a deficiency of bile; whether or not there is an insufficient amount of pancreatic juice; whether there is a probable insufficient secretion from the intestinal walls and glands or not; whether peristalsis is delayed and the motility of the bowels sluggish; whether there is blood extravasated from some portion of the stomach and intestine; whether there is an abnormal amount of mucus; and last whether or not there is pus. Abnormality in the feces will give indications as to the etiology of the condition and the *best line of treatment.* If it seems probable that the whole disturbance is in the stomach, or at least that a portion of the disturbance comes from the stomach, examination of a test breakfast by means of a stomach tube will show what part the stomach takes in the general disturbance that is present.

It will be conceded by every practitioner that if any of the above-named abnormalities can be determined by examination of the feces, it is certainly advisable; the only drawback is the difficulty with which such a determination is made. In other words, if an easy, quick method of making such a scientific examination can be offered, it will be adopted by the general practitioner.

The following method is one that has been devised by Dr. M. M. Scarbrough, of New Haven, instructor in pharmacology at the Yale Medical School. The daily diet which he suggests that a patient should receive for three days before the examination of the feces is to be made is as follows: One quart of milk, one-fourth pound of bread, one-half pound of potato, one-fourth pound chopped beef. This represents about 100 grams of albumin, about 110 grams of fat, and about 200 grams of carbohydrate, amounting to about 2,225 calories in heat value, enough to meet the requirements of a man at light work. The following is the menu in detail:

Breakfast:—One soft boiled egg, 2 slices of toast with butter, 1 bowl of oat-meal with sugar and cream, 1 glass of milk, and 1 cup of coffee. If coffee is not desired, another glass of milk may be substituted.

Dinner:—A quarter pound of finely chopped round steak (very slightly broiled so that most of it is rare) ½ pound of mashed potato, 2 slices of white bread or toast, plenty of butter, and 1 or 2 glasses of milk.

Supper:—Same as the breakfast.

A patient is put rigidly on the above diet for three or four days. At the beginning of the diet he is given a tablet or capsule containing 0.30 gram (5 grains) of pure willow charcoal. This dose of charcoal is repeated at the end of the diet. The consequent black stools from these two doses of charcoal will mark the beginning and end of the period of special diet. The length of time it takes the charcoal to go through the intestines will determine their activity and whether the food is delayed or not in its passage through the alimentary tract. The second dose of charcoal is useful only to determine whether the activity of the canal has changed during the rigid diet. The stool which is to be taken for examination should be at the end of the third 24-hour period of the diet and before the administration of the second dose of charcoal. The stool desired is collected in a wide-mouthed jar and examined immediately, and the examination may be divided into macroscopic, microscopic and chemical.

Macroscopically, under normal conditions, we find a soft-formed stool, light-brown in color and of uniform consistency. A liquid stool usually denotes a too rapid passage of food through the tract; a tarry stool indicates blood coming from the stomach or high up in the intestine. Flakes of mucus, blood, pus, etc., are pathologic. Next a piece of feces the size of a walnut is ground up in a mortar with a little water and then spread out on a glass plate in a thin layer. The normal feces appear perfectly homogeneous except for here and there small broken, brownish points of cellulose from the oatmeal eaten. In this preparation may be seen food remains which are abnormal. Firm whitish or yellowish strings of connective tissue, and small brown-colored rods of muscle fiber, appearing like splinters of wood, may be seen here and there, denoting improper digestion of the meat. Starch granules in the form of glassy transparent globules like sago grains, may be present and must be distinguished from shiny, ragged flakes of mucus.

The microscopic examination, which is made to confirm the preceding, is very simple. A small mass of feces is pressed out in a thin layer on a slide by means of a cover-glass. Normal excrement from the test-diet appears as a fine detritus of granules, globules and bacteria, interspersed here and there with fragments of muscle fibers, small, irregular, yellowish flakes of calcium salts and less numerous skeletal remains of potato cells, besides the chaffy particles from the oatmeal. On a second slide a small piece of feces is stirred up with two drops of a 35 per cent. solution of acetic acid, heated over a flame until bubbles arise, and then set to cool. The process causes a liberation of the free fatty acids which flock out on the surface of the preparation, giving a rough index to the amount of fat in the stool.

It should be remembered that fat is a united compound of a fatty acid radical and glycerin. Under the action of pancreatic secretion the glycerin is separated from the fatty acid radical. Then, and not before the glycerin is so separated, can the bile act on the fatty acid radical to change it into a fatty acid that can be absorbed. Without the action of bile the original fat can not be absorbed, and the fatty acid resulting from the breaking up of the fat from the action of the pancreatic juice also can not be absorbed. In the presence of potassium or sodium the fatty acid can be converted by means of the bile into a soap. It will thus be seen that, either from imperfect pancreatic juice or from imperfect bile, fat may not be absorbed, and will appear in the stools as such. If the pancreatic juice acts normally on a fatty food and the bile is not secreted or does not act, then crystals of fatty acids and perhaps soaps will appear in the feces.

On a third slide an iodin solution (liquor iodi compositus, Lugol's solution, diluted with equal part of water) is used, which stains the starch, yeast and other fungi that may be present. The microscopic examination may reveal the following pathologic components: fragments of muscle fibers large in size and in good state of preservation; clusters of undigested starch grains; numerous needles and crystals of fatty acids and soaps; and occasionally various fungi.

The chemical tests are very simple. The litmus reaction is taken; normal stools are faintly alkaline or at least feebly acid. Next a little of the stool is mixed with a strong bichlorid solution (a saturated solution of corrosive sublimate in water, which is, in cold water, not far from 7 per cent.); normal feces give a red reaction, while feces that have passed through the tract so rapidly that the bile has not been reduced give a greenish reaction. The bile should be digested in the intestine, if present; consequently the greenish color is abnormal and shows that undigested bile pigments have passed entirely through the intestinal tract. The last test is the amount of gas that the stool will give off. If there is produced a large amount of gas and the feces become acid it usually indicates an excess of carbohydrates in the stool; if there is produced a moderate amount of gas and the stool becomes alkaline and foul it usually indicates an excess of protein in the stool. The normal feces should produce only a small amount of gas with only slight change in reaction. An accurate gas determination can only be made after a portion of the feces has stood for 24 hours in a bottle so that the gas given off from the bacterial action in the fecal material, without the addition of any substance, may be collected and measured. This determination, therefore, takes time, requires a properly graduated and constructed bottle for the gas determination, and is hardly practical for the rapid clinical examination of the feces which is being described.

The significance of pathologic findings may now be briefly rehearsed. Mucus in the stool means the existence of an inflammatory condition of the mucous membrane. Almost always it comes from the large intestine or rectum. The mucus from the stomach and small intestine is dissolved by the digestive fluids unless the passage through the canal is very rapid. Unchanged bile pigment, as detected by the bichlorid test, indicates a very rapid passage of intestinal contents; absence of bile pigment denotes complete obstruction of the biliary duct. Excess of fat in the stool may be due to its incomplete digestion on account of a diminished amount of bile, or to a disturbance of the pancreatic secretion.

The finding of meat remains is of great significance. Connective tissue never appears in the feces after the test diet unless there is a disturbance of digestion in the stomach, a diminished gastric juice. The trouble once located in the stomach can be further studied by the well-known methods of gastric analysis. The other structures of the meat (the muscle fibers) are not digested in the stomach. Even in complete achylia gastrica muscle fragments never appear in the stool. The presence of muscle fibers in a good state of preservation always means trouble in the small intestine, due to one or more of the following conditions: the pancreatic juice may be insufficient; or the active enterokinase of the secretions of the small intestine may be absent; or, finally, there may be a marked hypermotility, too rapid peristalsis, of the small intestine, thus not allowing time for digestion of these elements. A method for the investigation of the exact cause of intestinal indigestion of meat fibers has not yet been satisfactorily worked out. However, as the nuclei of tissue cells are digested only by the pancreatic secretion, Schmidt has devised his nuclei test, which consists in giving a small cube of meat placed in a small porous silk bag. The bag almost always contains remains of the tissue after passing through the gastrointestinal tract. If undigested nuclei are present, it is safe to conclude that there is an unsatisfactory functioning of the pancreas.

The presence of starch elements indicates its incomplete digestion in the small intestine and shows a disturbance of the pancreatic secretion and of the intestinal juice. Insufficiency of starch digestion is further confirmed by the fermentation test and by the finding in the stool of organisms that stain blue or violet with iodin.

It seems to be a fact that when there is constipation in individuals otherwise well, that there are but few food fragments in the feces. Even the cellulose of the potato cells and of oatmeal disappear. This probably means that the longer time that these food products remain in the intestine, the more complete is the digestion. In such instances of constipation with otherwise good health there is often but little gas or fermentation discovered by examination of the feces. Constipation in such individuals is due to the too complete absorption of the liquid portion of the intestinal contents and such a complete digestion of food products as to inhibit the development of normal bacteria. Consequently, there is less gas and less liquid and the normal stimuli to peristalsis are absent. This form of constipation is generally improved by the agar-agar treatment. Agar-agar can be obtained in granulated form, and may be eaten in the morning with cream and sugar, similar to a cereal, and even bread may be made of agar-agar. Ordinary gelatin is also of advantage in this kind of constipation; also are ripe bananas. The action of these food products is mechanical; they absorb water, retain it, prevent the fecal debris from becoming dry, and give a larger bulk for normal peristalsis.

The absence or diminution of bile coloring matter in the stools of course points to deficient liver activity or to some obstruction to the bile ducts. If there is a large amount of mucus in the fecal matters, and if there are shreds of membrane or actual pus, it shows an abnormally increased secretion of mucus or an actual inflammation in some part of the alimentary canal. If there is much mucus or mucopus in the stools, it is generally due to catarrh of the large intestine. Such a condition generally gives frequent small bowel movements.

To a small portion of feces in a test tube add three drops of freshly made tincture of guaiac, then add a layer of half an inch, or so, of peroxid of hydrogen solution. If blood is present, there will be a ring of blue form between the peroxid solution and the fecal solution. If this is thoroughly shaken, of course the whole of the peroxid solution becomes blue if blood is present. This is a test for occult blood, *i. e.*, hidden or digested blood. Blood in large amount, or if evident macroscopically, requires no such test. The diagnostic findings and the indications for treatment may be summed up as follows:

1. If the charcoal is slow in passing through the alimentary canal, *i. e.*, more than thirty-six hours after ingestion, intestinal peristalsis is sluggish.
2. If the fecal matters are very dry, there is too great absorption of liquid from the intestines.
3. If the stools are very liquid, there is generally too rapid peristalsis.
4. If the fecal matters are distinctly or very acid, there is an imperfect intestinal digestion.
5. If there is much gas in the feces, there is maldigestion of some kind; it may be purin maldigestion or carbohydrate maldigestion. Whichever it is otherwise determined that it is, that particular kind of food should be limited.
6. If there is undigested connective tissue found microscopically, the trouble lies in the stomach, which should then be studied by means of the test breakfast and examination of the stomach contents withdrawn an hour after the test breakfast has been taken. If there are undigested muscle fibers present, there is insufficient pancreatic secretion, and meat should be diminished or temporarily withdrawn from the diet.
7. If there is a large amount of undigested starch particles, the pancreatic juice is deficient, at least in its starch digestion properties; consequently the starch in the diet should be diminished.
8. If the bile pigments are absent, of course the bile is not secreted (or excreted) into the alimentary tract. If there is a large amount of bubbling from the liberation of fatty acids during the acetic acid test, or if there is a large amount of fat in the stool, it would show deficient bile secretion, and the amount of fat ingested should be greatly diminished.
9. Abnormal bacteria, or an abnormal amount of bacteria, or specific bacteria would suggest various diets, bowel antiseptics, purgings, and various systemic treatments, depending on the findings.
10. Much mucus or pus would suggest the treatment, depending on the region from which it was supposed to come; colon washings or colon treatments, if the colon was at fault.
11. If there is blood in the stool, evident or occult, it must be determined, if possible, from what part of the tract it comes.

FLIES AND TYPHOID FEVER

It is sometimes easier to implant a new idea in the human mind than to extract it or modify it when it has once taken firm root. The notion that bad smells from faulty sewers give rise to specific infections such as diphtheria and typhoid fever, or that piles of garbage "breed disease" are cases in point. In the public mind methods of garbage disposal and elaborate plumbing ordinances often loom large as the chief weapons of combating disease. Too often attention is diverted from *really significant* and tangible dangers to health by the cry that the garbage dump or the sewage manhole is emitting vile odors. It is of course well known to physicians that there is no evidence that disease can be spread by odors, although foul air may possibly impair health and render the body less resistant to disease.

Many sanitarians are beginning to fear that a similar misapplication or misunderstanding of the relation of the house-fly to typhoid fever is coming about. No one questions that the house-fly is an unmitigated nuisance. Neither is there any doubt that under certain conditions such as prevail in military or mining camps or on many a country farm, or even in cities that allow the crude type of privy, the house-fly is an exceedingly important agent in the transmission of infection. This has been abundantly proved. There is observable, however, a tendency to assume a connection much wider than this and to attribute to fly infection a portion, sometimes the major portion, of the typhoid fever occurring in large and well-sewered cities. Several instances of this misguided enthusiasm have come to notice within the last few months. It need hardly be pointed out that the house-fly, no matter how disgusting its origin or habits, cannot convey the specific germ of typhoid fever to any food substance unless it has access both to food substance and to typhoid germ. Those amateur investigators who assume that they have discovered the origin of a typhoid epidemic if they observe a few piles of horse-manure in the alleys of a city take a wide leap over logical difficulties. Their mode of reasoning seems to be this: Flies can breed in horse dung, flies can convey typhoid fever, therefore flies bred in these dungheaps have caused or are about to cause typhoid fever. One other essential condition, namely, the existence of infected material to which the flies have access, is left out of account in such hasty judgments. As a matter of fact, grave as is the danger of fly transmission of typhoid under rural conditions, it does not seem to be an important factor in the production of urban typhoid. As is well known, the intensive study of typhoid fever in Washington, D. C., which extended over several years, yielded no evidence that fly-transmission had any noteworthy share in typhoid fever causation in that city.

One of the most experienced American health officers has taken a decided stand on this question in a book recently published.[1] While recognizing the desirability of treating garbage in such a way as to prevent a nuisance, and admitting the possibility of fly-borne infection where open privy vaults exist, he declares very plainly that "there is no evidence that in the average city the house-fly is a factor of great moment in the dissemination of disease." There can be no doubt that in any reasonably clean and well-sewered city the cases of typhoid infection due to direct fly transmission are relatively very few compared with the number due to water, to milk and to contact (including contact with carriers). As one writer has said in discussing this question "we need more scientific knowledge and less repetitious babble of sentiment in dealing with flies or any other nuisance."

SUNLIGHT, BAREHEADEDNESS AND BALDNESS

Recently we called attention to the observations of Grawitz[2] that too much indulgence in sun baths is prejudicial to the human organism and causes irritability and nervousness, cardiac and circulatory disturbances, and more or less serious dermal lesions. Recent observations confirm these findings and show that the skin and its appendages are peculiarly susceptible to the sun's rays.

During the past few summers there has been a wide-spread and growing tendency among young people to discard head coverings of all kinds, and to go about under the open sun bareheaded. Indeed in college communities, the bare-head habit has not been limited to summer, and it has apparently been considered modish to go about hatless in weather which caused older and less faddish heads to seek the shelter of furs and ear muffs. This custom has received not a little encouragement from the wide-spread belief, which is probably well warranted, that baldness is commonly caused by the obstruction to the circulation of the scalp by the pressure of hat-bands; therefore to escape this unwholesome pressure and at the same time to secure the stimulating effects of sunlight seemed an ideal method for insuring a permanent and luxuriant head of hair.

---

[1] Chapin, Charles V.: Sources and Modes of Infection, New York, 1910.

[2] THE JOURNAL, Aug. 6, 1910, p. 506.

That the results of the habit are not always so favorable, but often quite the reverse, was pointed out at the meeting of the American Dermatological Association in Boston by Dr. George F. Harding and others.[2] Dr. Harding said that his deductions from the observation of 312 cases of alopecia in young people between the ages of twelve and twenty years, would indicate that exposure to the sun was harmful rather than beneficial to the hair and scalp. The alopecia affected chiefly blonds (293 of the 312 cases), presumably because of the finer texture and lack of pigmentary protection, and when following a single season's exposure showed itself from four to six weeks after the return of the patients from seaside or country to the city. If the custom is persisted in for several seasons the baldness becomes marked and the prognosis unfavorable. Other dermatologists concurred in this unfavorable opinion of the influence of direct sunlight on the scalp, and pointed out the similarity of the effects of the highly actinic rays of the sun and the *x*-rays, whose depilatory powers are well recognized and often used.

The time was when we thought that man could not possibly get too much sunlight, but we are learning, especially through our friends in the tropics, that for the white man at least the limit of advantageous exposure to the sun is quickly reached. It is all a question of dosage, and those who would go back to Nature and the bare-headed state of man must be warned of the necessity of moderation even in this simple indulgence.

MEDICAL RESEARCH AND MEDICAL EDUCATION

Elsewhere in this issue comment is made on a recent gift to a medical teaching institution, for the encouragement of medical research. This aid to the investigation of new problems is gratifying. Through medical research the known facts connected with medicine have increased to an enormous extent, and many practical methods of prevention, diagnosis and treatment of disease have been evolved. The good work is still going on. But it should not stop here. For while it is impossible to give too much financial encouragement to medical research, still it is to be regretted that the importance of encouraging a higher standard of medical education is not being appreciated to a like extent. It does not seem to be realized that this newer knowledge in medicine is of little worth unless it be practically applied by physicians, and that its vast importance requires of them far broader knowledge, and therefore a much higher standard of education than was necessary before the recent remarkable development of scientific medicine.

Medical progress has been so rapid that medical schools have found difficulty in keeping pace with it. The leading schools have been striving to provide a course that would meet the requirements. The medical course has been extended from two years of six or seven months each to four years of eight or nine months each. Such subjects as bacteriology, pathology, physiologic chemistry, pharmacology, etc., hardly thought of a little while ago, have become fundamental and essential.

And so it has developed that to teach modern medicine requires the college to provide extensively equipped laboratories and to employ specially trained teachers with salaries that will permit them to devote their entire time to the work. But this means an enormous additional expense—so enormous that many teaching institutions have been unable to meet it.

Again, the modern medical course requires that the students who enter, in order to master the newer subjects, must have a much broader preliminary training than was formerly necessary. And this deters many who would otherwise enter on the study of medicine.

On the one hand, therefore, the medical school is put to an enormously increased expense; while on the other hand, by the prolonged medical course and by exacting higher entrance requirements, the number of students who can meet the requirements has been greatly reduced. Hence it has become financially impossible for a medical school dependent solely on students' fees to teach modern medicine as it should be taught. Medical schools to-day simply must have outside support, either by private endowment or by state aid.

It is to be hoped, therefore, that the recent generous gifts for medical research merely foreshadow equally generous gifts for medical education, so that the knowledge that results from medical research may be practically applied in the prevention of sickness and in the treatment of disease. No investment will bring greater returns in the extension of health and happiness than financial support given to those medical schools which are honestly and unselfishly striving to educate men for the practice of modern medicine.

Current Comment

MEDICAL EXPERT TESTIMONY

Medical expert testimony is a puzzling problem for physicians, lawyers and judges. It has been repeatedly discussed at various medical meetings, at the annual sessions of the National Legislative Council of the American Medical Association and at the meetings of the American Bar Association. An effort is now being made in Missouri to secure some tangible results, through cooperation between the State Medical Association and the Missouri Bar Association. A joint committee representing both of these bodies has drafted a proposed law with a view to improving the status of expert medical testimony in the courts. The bill, if passed, will empower any judge of any court of record, on his own motion or on that of either party in the case, when the ends of justice seem to require it, to appoint one or more disinterested, skilled persons to serve as expert witnesses, the fees of such witnesses to be fixed by the judge and to be paid by the party asking for the appointment of such experts. In criminal cases, on the request of the defendant, expert witnesses may be furnished at the expense of the state. The bill provides that these witnesses shall examine such persons, matters or things as the court shall direct, and report their findings in writing, not as evidence, but as a basis for their examination by the court or by counsel for either party. They will not be regarded as witnesses for either party. In personal injury suits, the judge may require the person alleged as injured to submit to a reasonable examination, physical or mental, by the experts so appointed. There are at present only two states which have enacted an expert testimony law, Michigan and Rhode Island. No one will deny that the present condition of medical expert testimony is most unsatisfactory. The solution of the problem will require the united efforts of both the medical and legal professions. Neither alone can solve it. The recognition of this fact by the Missouri State Medical Association, and the effort to cooperate with the State Bar Association are steps in the right direction.

THE CHICAGO CLINICAL MEETING

A series of surgical clinics, carefully planned and covering two weeks, has just terminated in Chicago. In an item in the news department appears the statement that perhaps 1,000 surgeons from outside the city have attended these clinics. This remarkable showing clearly demonstrates three things: first, that physicians are to-day more anxious than ever to fit themselves for better work and are willing to spend time and money for that purpose; second, that owing to multiplication of societies and meetings, the writing and reading of papers have been relatively overdone and that fewer and better meetings with fewer, shorter and better papers and more clinics should be the aim; third, that the medical profession of Chicago to-day faces an almost unprecedented opportunity to make that city one of the greatest medical educational centers of the country.

INTERSTATE COMMERCE IN MEDICAL SERVICES

The power of the state to regulate the practice of medicine through the exercise of its police power has been repeatedly stated and emphasized. As the practice of medicine is ordinarily a local function, it has been generally assumed that state regulation is sufficient. A case has recently come to light, however, which shows that in regulating the practice of medicine, as in regulating railroads and express companies, there must be something additional and supplementary to state regulation, if the public is to be protected. In the case referred to, an individual residing in one of our larger cities, who is not licensed and who cannot obtain a license to practice medicine in the state in which he lives, has been doing an extensive business by mail with "patients" located in other states; he has been treating their ailments and prescribing for them by mail, regardless of the fact that he was not legally qualified to practice medicine either in the state in which he lives or in the various states in which his "patients" live. It is apparently difficult if not impossible to indict him in either state. Under existing federal laws, he can, if proven guilty, be punished for using the United States mails for fraudulent purposes, but he cannot be arraigned in a federal court for practicing medicine illegally, since there is no federal enactment regulating the interstate practice of medicine. It is a legal axiom in this country that the power of the federal government begins where the power of the state ends. It seems clear that there should be some way of preventing a citizen of one state from performing any act in another state which he could not legally do in the state in which he resides.

ANOTHER GIFT FOR MEDICAL RESEARCH

Medical research has received much encouragement of late through generous donations from men of wealth. Every week or two announcements are made of large gifts for the endowing of this important work. The latest instance is the gift of $200,000 from Mr. James A. Patten to endow a chair of medical research at the Northwestern University Medical School, Chicago. The chief object of this gift is the investigation of tuberculosis, a brother of the donor having recently died of this disease. By a wise provision, however, the fund will not be limited to this particular work but will be used in any field which promises results in preventive medicine and in the treatment of disease. The gift is considered adequate to secure the services of a skilled investigator and to initiate the work, although further funds will doubtless be available as the work proceeds.

CHINESE HAIR AND AMERICAN RATS

The British Consul at Swatow, China, reports that Chinese exports of human hair have nearly doubled in value, the cause being the change in style of ladies' hairdressing in America and Europe. The Chinese have not been slow to take advantage of this sudden development of the business. The consul states that all classes of natives have invested money in the business, and that the poor have found a paying occupation in collecting combings and preparing them for the market. In view of the alleged fondness of some Chinese for rats, one could almost construct a joke out of this exportation of hair for "rats" for American and European women.

THE PLAGUE IN ENGLAND

Mention is made by our London correspondent in this issue of the occurrence of a number of cases of what was supposed to be pneumonic plague. According to the Local Government Board,[1] there occurred four deaths at Freston in Suffolk, which, it was believed, could be ascribed to plague of the pneumonic type. A bacteriologic examination of material taken from two of the patients apparently confirmed the clinical diagnosis. Subsequently, rats and hares found dead or dying in the same locality were examined, and found to be infected with plague. As result of these findings, a very systematic effort was inaugurated to destroy rats and remove accumulations of refuse. The result has been a most satisfactory one, no cases of human illness suspicious of plague having occurred since the latter part of September. Fortunately, public apprehension was not aroused by these deaths; in fact, little opportunity was given the public to become frightened. The local health authorities proceeded with the work of prevention so quickly and so admirably that all danger of spread of the contagion had passed before the presence of the plague became generally known. This certainly was most desirable, inasmuch as it left the authorities unhampered in their endeavor to check the contagion.

---

ROSES INSTEAD OF TAGS

We are becoming accustomed to the use of the little stamps sold at Christmas time, the proceeds of which go to aid in the eradication of tuberculosis. In many of our cities "tag day" has become an established institution as a means of raising money for local charities. These methods of raising funds for worthy causes have been accepted by the public to such an extent that on a recent "tag day" in one of our large cities, it was practically impossible by evening to find any one on the down-town streets who did not wear a little pasteboard tag as an evidence of contribution to the designated charities. While our methods are effective so far as results are concerned, our European neighbors have evidently improved on the American plan, from an esthetic standpoint. Laurence Sterne observed, long ago, in another connection, that "they do these things better in France." Evidently, Belgium has profited by intercourse with her artistic neighbor. A dispatch from Brussels states that the fight against tuberculosis in that country is aided by a "rose day," on which occasion the *rose de la reine* is the decoration which everyone is expected to wear. Sunday, the queen's day, is designated as rose day and hundreds of thousands of little roses, sold for the benefit of the Oeuvre contre la Tuberculose, are seen in buttonholes and on dresses and hats. One of the three rose bazaars in Brussels sold this year over 150,000 roses and would have sold more had it been possible to secure them. This plan of raising funds for a worthy object is practically the same as ours, but the substitution of the rose for the pasteboard tag is a beautiful improvement which is commended to our charity workers for consideration.

Medical News

COLORADO

Gifts to Hospitals.—The National Jewish Hospital for Consumptives and the Jewish Relief Society for Consumptives each received a gift of $1,000 from Louis J. Aaron, Pittsburg, Pa.

New Building for Physicians.—The new Metropolitan Building, Sixteenth Street and Court Place, which has been adopted for the permanent home of the Denver City and County Society, is ready for occupancy. About 100 physicians and dentists have moved or are moving into the building. The building will also contain the library of the society and a lecture room.

Personal.—Dr. Eleanor Lawney, Denver, has been elected president of the board of directors of the Visiting Nurses' Association.——Dr. John R. Robinson, Colorado Springs, who was operated on for appendicitis, is reported to be improving.——Dr. John W. Webb, Denver, on trial for the murder of Mrs. Georgia Slaughter Erby, for an alleged illegal operation, was found not guilty by the jury, November 4.

CONNECTICUT

Personal.—Dr. John E. Farrell, Waterbury, announces that he will hereafter limit his practice to the treatment of diseases of children.

Health Board Needs.—The Board of Public Health of Waterbury has asked for an appropriation of $11,710 for its 1911 expenses, an increase over the appropriation for this year of $5,210. The estimated expense of garbage removal for the year is $23,000.

Gifts to Medical Society and Hospital.—By the will of Mrs. Mary Bacon, widow of Dr. William T. Bacon, Hartford, $100,000 is devised to the Hartford Medical Society, and $5,000 to the Hartford Hospital to provide for a free bed for patients suffering from diseases of the eye or ear.

GEORGIA

Wish New Hospital for Rome.—Several physicians of Rome appeared before the city council recently, and offered to erect a city hospital to cost $50,000, provided the city would provide for the maintenance of the institution.

Entrance Requirements.—Entrance requirements to medical colleges was an interesting part of the program of the Association of Colleges and Preparatory Schools of the Southern States which held its sixteenth annual meeting at the University of Georgia, Athens, November 3 to 5. Papers on immediate and ultimate standards of preliminary education for admission to medical schools were presented by Dr. Richard H. Whitehead, dean of the Medical Department of the University of Virginia and Dr. Nathan P. Colwell, secretary of the Council on Medical Education of the American Medical Association. A number of physicians were present including Dr. Alfred L. Gray and Dr. J. Allison Hodges of the University College of Medicine, Richmond, Va., who participated in the discussion.

Personal.—Dr. John H. Phillips, Oakhurst, Atlanta, who was arraigned November 1, charged with violating the contagious disease ordinance by tearing down a diphtheria card from a house, is said to have been found guilty, and fined $25 and costs.——In the case of George Williamson, a farmer near Butler, who sued Dr. Wanzie W. Edwards, for alleged malicious malpractice, the jury, after being out fifteen minutes, brought in a verdict in favor of Dr. Edwards.——Dr. Leo Reich has been appointed lecturer on diseases of the skin in the Medical College of Georgia, Augusta, and also consulting physician to the Children's Hospital.——Dr. J. Scott Todd, Atlanta, who underwent operation in St. Joseph's Infirmary recently is reported to be doing well.——Dr. William H. Doughty has succeeded Dr. Joseph E. Allen as dean of the Medical College of Georgia, Augusta.——Dr. William J. McNaughton, Covena, Swainsboro, charged with the murder of Fred Flanders, is said to have been found guilty and sentenced to be hanged December 9. A motion for a new trial has been filed.

ILLINOIS

Personal.—Dr. Harold D. Singer, Hospital, has sailed for England.——Dr. Joseph De Silva and Albert N. Mueller have been appointed trustees of the Rock Island Municipal Tuberculosis Hospital.——Dr. Sumner M. Miller has been elected president of the medical staff of Deaconess Hospital, Peoria.

State Board Decisions.—The Illinois State Board of Health at its last meeting again declared the St. Louis College of Physicians and Surgeons not in good standing.——On November 3, the superior court of Cook County dismissed the personal damage suit brought by the National Medical University against the State Board of Health for its action in declaring the National Medical University not in good standing. The plaintiff appealed to the appellate court.

Illinois Physicians' Meeting.—The Aesculapian Society of the Wabash Valley held its sixty-fourth annual meeting in Paris, October 27, and elected the following officers: president, Dr. Finis E. Bell, Mattoon; vice-president, Dr. H. P. Canatta, Vernon; secretary-treasurer, Dr. Herbert N. Rafferty, Robinson, and censors, Drs. Albert T. Summers, Mattoon, Frank Dunham, Robinson, Myron A. Boor, Terre Haute, Ind., William H. Ten Broeck, Paris, and Stephen C. Glidden, Danville. The next semi-annual meeting will be held in Danville in April.——

The annual meeting of the Western Medical Society of Illinois was held in Alton, October 28. The following officers were elected: Dr. N. Gerhard Taphorn, Alton, president; Drs. Levin H. A. Nickerson, Quincy, and Elmer L Crouch, Jacksonville, vice-presidents, and Dr. William P. Duncan, Jacksonville, secretary-treasurer.——The Illinois State Hospital Medical Association was organized in Chicago, October 27. Dr. Harold D. Singer, director of the Psychopathic Institute at the Kankakee State Hospital, was elected president, and Dr. Edward A. Foley, of the Anna State Hospital, secretary.——The Southern Illinois Medical Association held its annual meeting in Centralia, November 3 and 4, and selected Mount Vernon as its place of meeting for next year. The following officers were elected: president, Dr. Edward W. Fiegenbaum, Edwardsville, vice-presidents, Drs. Andy Hall, Mount Vernon, and Harry E. Wilson, Centralia; secretary, Dr. Charles W. Lillie, East St. Louis; assistant secretary, Dr. Harry W. Dale, McLeansboro, and treasurer, Dr Alexis T. Telford, Olney.——At the ninety first annual meeting of the Fox River Valley Medical Association, held in Aurora, November 8, the following officers were elected: president, Dr. Charles H. Franz, Aurora; vice president, Dr. Dwight E. Burlingame, Elgin; secretary-treasurer, Dr. William H. Schwingel, Aurora; censors, Drs. James A. Rutledge, Elgin, William P. Sherman, Aurora, and George W. Haan, Aurora; delegate to the Illinois State Medical Society, Dr George F. Allen, Aurora, and alternate, Dr. Frank H. Jenks, Elgin.

Chicago

Higher Entrance Requirements.—The dean of Northwestern University Medical School announces that hereafter the institution will require two years of collegiate work as requisite for admission instead of one year as heretofore.

Physician Shot.—Dr. Jacques Holinger, a specialist in diseases of the throat, while in his office November 9, was seriously wounded by a patient, who shot him three times, once through the nose and twice through the arm. The patient then killed himself. Dr. Holinger is progressing favorably.

Plan for Open Air Schools.—Members of the Chicago Permanent School Extension Committee, composed of delegates of ninety women's clubs of Cook County passed resolutions at its meeting, held in Chicago, October 29, to begin the systematic work of introducing open-air school rooms in as many Chicago schools as possible. The committee furthermore decided to raise funds to defray the expenses of providing the supplementary food and clothing for the children who are to be given the open-air instruction and treatment.

The Clinical Convention.—Chicago's medical population has been temporarily increased by nearly 1,000 physicians from all over the country who have been in attendance on the series of clinics held by the surgeons of Chicago in most of the hospitals, colleges and postgraduate schools. In connection with the clinics, special meetings of the various medical societies of the city are being held, at which many eminent surgeons from outside of Chicago are appearing on the programs. The occasion has furnished many practitioners the opportunity to refresh their knowledge of the details of many operations One valuable feature has been a series of reviews of "borderland surgery," in which were discussed the differential diagnoses of many conditions in which it is often difficult to determine whether or not operation should be performed Some of the prominent subjects taken up have been repair of intestinal wounds, grafting and transplanting, blood-vessel anastomosis (on which an article appears in this issue of The Journal), correction of results of infantile paralysis, removal of goiter, Cesarean section, wiring of fractures, etc. To give a list of those who have held clinics and assisted in them would be almost to give a catalogue of the active professors of surgery, hospital surgical staffs, etc., of the city, so general has been the cooperation, while a list of the subjects covered would rival the table of contents of an up to date treatise on surgery. Dr. Franklin H. Martin and those who have assisted him are being warmly congratulated on the success of the clinics. Some of those who were most optimistic in advance have been surprised to see how generally the plan has been taken up and carried through. Medical men have come from the Atlantic Coast and the Pacific States, from the South and from the North. One pleasant feature made possible by the presence here of many prominent surgeons from other cities has been the banquets, receptions and smokers given in their honor

INDIANA

Indianapolis to Open School for Defectives.—The City Board of Health of Indianapolis expects to open a school for defectives and to segregate all children whose eyesight or hearing may be impaired or who are mentally incapable of keeping pace with the brighter pupils.

Young Physicians Meet.—The Younger Physicians' Club of Indianapolis, which met October 28, reelected the following officers president, Dr. Alfred Henry; vice-president, Dr. Harrison S. Thurston, and secretary-treasurer, Dr. John H. Eberwein This is said to be the only social medical society in Indiana and holds five meetings a year, and at each a special talk is given on a subject relating to medical science, followed by vaudeville and smoker.

Personal.—Drs. Daniel S. Quickel and B. H. Reed, Anderson, were painfully injured in an automobile accident, November 2——The office of Dr. George W. Brown, Frankfort, was damaged by fire November 9.——Dr. Jesse M. Jones, Cataract, suffered a cerebral hemorrhage recently.——Dr. Joseph R. Whalen, Carlisle, is reported to be critically ill with cerebral hemorrhage.——Dr. Lewis N. Davis, Farmland, was painfully injured by the explosion of a medicine bottle, November 6.

Communicable Diseases.—Infantile paralysis has been reported from a number of cities in the state. Logansport alone has more than a dozen cases, and strict sanitary precautions have been taken to prevent an epidemic. Recent analysis of the city water supply shows a large number of colon bacilli. The city health authorities are progressive and are endeavoring to stamp out both scarlet fever and diphtheria, which have lately appeared in epidemic form. Notice has been served on the school board and city council that unless another high school building be secured within thirty days, the present school will be closed. The board of health has stopped two "rummage" sales which were believed to spread infection. Hereafter all clothing at "rummage" sales must be previously sterilized.

Health Clubs to be Organized.—Under the patronage of Dr. John N. Hurty, secretary of the State Board of Health, health clubs are being organized throughout the state. The first was organized at Brazil with a membership of thirty. The clubs devote much of their time to the study of hygiene, and to giving assistance to state and local health authorities in the enforcement of public health laws. Health days are planned to be held once or twice each year, in each of the public schools, and on these days teachers will be asked to address the students on hygiene and sanitation and the necessity of keeping back yards and alleys clean. Health weeks are to be held throughout the state, commencing in Warsaw, following which the different county seats will be visited. The state board will place specimens and charts on exhibition and give addresses on the manner of the prevention of diseases, more particularly tuberculosis. Dr William F. King, Columbia City is in charge of the work The first rural medical and dental inspection of schools was taken November 3 around Princetown, Ind Medical inspection has been so successful in cities that school patrons in the rural districts have petitioned for it.

KENTUCKY

Tuberculosis Cottage Built by Fraternal Order.—A completely equipped shack for the treatment of tuberculosis is to be erected on the grounds of the Hazelwood Sanatorium by the Louisville lodge of Elks, to cost about $4,000.

Reverses Order of Board of Health.—Governor Willson is said to have ordered that a license be granted to Dr. Frank A. Clark, Newport, who was refused a license to practice medicine by the State Board of Health, because, under the law, the school from which Dr. Clark was graduated is not recognized An appeal was taken to the governor.

Personal.—Dr. Isadore N. Bloom has been elected a school commissioner of Louisville——Dr. John D. Jackson, Danville, has decided to retire and will eventually locate in southern California——Dr. George P. Beutel, Jr., Louisville, has returned from abroad——Dr. W. Ed. Grant, health officer of Louisville, has gone to Pass Christian, Miss., for a month on account of his health.

New Hospital.—The vote in Louisville for the hospital bond proposition received more than the necessary two thirds vote Bonds for $1,000,000 will be issued by the Hospital Commission and active work will be begun for the plans at once. The hospital building will be torn down, the sick of the city being cared for in private institutions, and the new hospital will be erected on the present site The validity of the vote for the bond issue is to be tested by the courts by a friendly suit.

Tuberculosis Dispensary Busy.—There are at present 300 patients under the care of the dispensary of the Louisville Anti-tuberculosis Association, and it is estimated that there are 2,500 cases of tuberculosis in the city. New cases are being enrolled at the dispensary at the rate of 900 a year. Of the six nurses now on duty, one is at the tuberculosis Day Camp, the tuberculosis annex of the City Hospital; one is giving a course of lectures in the public schools of the city, and one follows up all deaths to see to the fumigation of the premises and to secure for the vital statistics bureau of the health department such sociologic information as is required. More than 1,000 visits monthly are made by the nurses.

Fireworks Ordinance.—At the last meeting of the Louisville General Council an ordinance was introduced prohibiting the sale of giant firecrackers, toy pistols, blank cartridges, explosive canes, ammunition for the canes and all explosives containing chlorate of potash, and providing as a penalty for violation thereof a fine of any sum up to $100 and a jail sentence up to thirty days, or both, at the discretion of the judge. The author of the ordinance stated that this committee had conferred with all the prominent dealers in fireworks in the city and that they were in favor of the passage of the ordinance. One councilman, in opposing the ordinance, said in substance that he was in favor of giving the small boy all the opportunity he desired to celebrate the patriotic holidays as he might please. He admitted that there had been a deplorable loss of life throughout the country in the hands of celebrators, but he tried to argue that such results were necessary to the greater good of instilling patriotism in the hearts of the American youth and giving him the knowledge of firearms and explosives. The measure passed by a vote of fourteen to six, and then was referred to the upper board and by that board to the cemeteries committee.

MARYLAND

Anti-Spitting Ordinance Passed.—The city council of Lonaconing has passed an anti-spitting ordinance with penalty of a fine of $1 to $10 or imprisonment not to exceed fifteen days.

Medical Society Election.—Washington County Medical Society, at its annual meeting, November 10, elected the following officers: Dr. William A. Quinn, Chewsville, president; Dr. J. Royer Laughlin, Hagerstown, vice-president; Dr. Samuel M. Wagaman, Hagerstown, secretary, and Dr. Luther H. Keller, Hagerstown, censor.

Baltimore

Founds Medical Scholarship.—Dr. J. Randolph Winslow has given $2,500 to found a medical scholarship at the University of Maryland, to be conferred on some worthy student of the second, third, or fourth year class.

Abbott Lectures.—Prof. Alexander C. Abbott, of the University of Pennsylvania, delivered two lectures at the University of Maryland, November 9 and 10, on "The Functions of the Municipality in Public Preventive Medicine" and "Interdependence Between the Laboratory and the Clinical Investigators."

NEW YORK

Annual Reports Issued.—The annual reports of the president and treasurer of Cornell University were issued November 12. In it President Schurman presents in his forceful way the various problems of research, the teacher, the student, the curriculum and university finances.

Another Tuberculosis Sanitarium.—At a recent meeting of the Poughkeepsie Academy of Medicine resolutions were adopted indorsing the action of the Board of Health of the city of Poughkeepsie in making a move to establish a tuberculosis hospital on the Pendell farm. Dr. Alva L. Peckham was elected president of the institution.

Increase in Insanity.—According to the report of the State Lunacy Commission, the number of insane in the state in hospitals has increased during the past twenty years from 16.006 to 32,650. In recent years the annual increase has been about 1,200 patients. The commission states that the rate to persons paying for the care of relatives in the state hospitals has been increased from $3.50 to $5.00 a week.

Precautions Against Typhoid Urged.—The monthly bulletin of the State Department of Health publishes a special warning to health officers, advising them to exercise more than usual precautions against typhoid fever, as the first rains after the prolonged drought may wash infected material into water supplies. It is suggested that local health boards advise consumers to boil their water. The department also urges immediate notification to the local health officer if any patient is suspected of having cholera.

Lunacy Board Retrenches.—The State Lunacy Commission recommends radical steps for the purpose of cutting down expenses. It is suggested that a single commissioner be substituted for the three present members. It is also suggested that instead of each hospital having its own attorney the work be assigned to deputies in the attorney-general's office. The commission also proposes to replace the three alienists who examine immigrants at the port of New York, by one alienist with two lay deputies. The insane in the state are increasing at the rate of about 1,200 per year and cost the state $8,000,000 last year.

September Mortality.—The death rate in the state for September was 15.4 per 1,000, the lowest for any month thus far for the year, excepting June, when there were 350 fewer deaths than in September, when there were 11,233. There were 1,400 deaths of infants under two years of age as against 600 for June. Epidemic diseases caused 4.2 per cent. of the deaths of September. Typhoid fever has been the chief contributor to this, causing 185 of the 476 deaths from these causes. Diphtheria has only 100 deaths while in the months preceding the deaths from this cause numbered from 150 to 250. Poliomyelitis has been the reported cause of 21 deaths and numerous epidemics exist.

Rabies in New York State.—Statistics of the State Department of Health show that this state has for 2 or 3 years been suffering from an epidemic of rabies. Statistics compiled up to April 1, 1910, show that at that time the disease existed in sixteen counties, and the State Department had quarantined two villages, seven cities and fifty-one townships. During the years 1908, 1909 and 1910, to date, the records show that 105 persons have been bitten by rabid animals, 12 of whom died; 10 horses were bitten, of which 5 died; 68 cattle were bitten, of which 38 died; 11 swine bitten, 10 of which died. This does not include hundreds of dogs that have died of rabies or have been killed because of showing some symptoms of the disease. These figures are very large when the fact that the disease has been stamped out by proper methods of control in some other countries is considered.

Society Meetings.—The annual meeting of the Medical Association of Central New York was held in Syracuse, October 20 and 21. Dr. Wesley T. Mulligan, Rochester, was elected president; Dr. William G. Johnson, vice-president; John J. Buettner, Syracuse, secretary, and Dr. Charles O. Boswell, Rochester, treasurer. The next meeting will be held in Rochester. ——The Fifth District Branch of the Medical Society of the State of New York held its annual meeting in Syracuse, October 19, and the following officers were elected: president, Dr. Arthur A. Gillette, Rome; vice-president, Dr. Conway W. Frost, Utica; secretary, Dr. Frederick, H. Flaherty, Syracuse, and treasurer, Dr. Henry A. Hoyt, Watertown.——At the annual meeting of the Orleans County Medical Society, held in Albion, October 4, the following officers were elected: president, Dr. John H. Taylor, Holley; vice-president, Dr. Fremont W. Scott, Medina; secretary-treasurer, Dr. Ralph E. Brodie, Albion, and censors, Drs. Edward Munson, Medina, John Dugan, Albion, and George Post, Holly (since deceased). ——The Eighth District Branch of the Medical Society of the State of New York held its meeting in Buffalo, September 30, and elected the following officers: president, Dr. Thomas H. McKee, Buffalo; vice-presidents, Drs Henry A. Eastman, Jamestown, and Arthur G. Bennett, Buffalo; secretary, Dr. Carl S. Tompkins, Buffalo, and treasurer, Dr. Charles A. Wall, Buffalo.

New York City

Awarded Verdict.—A jury in the supreme court before Justice Ford is said to have returned a verdict of $3,000 in favor of Mrs. Freda Lazarowitz, who sued Dr. Philip Sussman, alleging lack of care in the use of chloroform was responsible for the death of her son.

Measles on Ocean Steamer.—The steamer *Ultonia*, which reached New York from Trieste, November 3, was detained at quarantine on account of measles. Fifty passengers, including many mothers and children, were transferred to Hoffman Island for observation and treatment.

Tuberculosis Hospital of Metropolitan Life Insurance Company.—This company has decided to change the location of its proposed tuberculosis sanitarium from Sullivan to Saratoga County. An application has been filed with the State Health Commissioner for permission to construct a sanitarium at Mount McGregor.

Harvey Lecture.—The third of the present course of Harvey lectures to be delivered on November 19 in Hosack Hall, New York Academy of Medicine, at 8:15, is by Prof. Jacques Loeb of the Rockefeller Institute of Medical Research, on "The Prevention of the Toxic Action of Various Agencies Through the Prevention of Oxidation in the Cell."

Street and Yard Singing.—Numerous complaints have been received by the health board of the annoyance caused by singing in back yards and streets, which under the present ordinance the health department is powerless to remedy. Some of the health board officers voice the opinion that the ordinance should be so amended as to do away with the singing nuisance and also enforce quiet in the neighborhood of schools.

Personal.—Dr. Edmund L. Cocks has been appointed consulting dermatologist to Harlem Hospital.——Dr. J. Riddle Goffe has obtained from the appellate division of the supreme court the reversal of the judgment for $9,201.70 in favor of Ella H. Brown, who claimed "careless and negligent treatment." Justice Scott in presenting the opinion of the supreme court stated that Dr. Goffe was not allowed at the trial to answer a perfectly proper question as to what instructions he had given the hospital staff of physicians with reference to the care of the plaintiff.

City Druggists Protest.—Delegates from the societies representing all the retail druggists in this city met recently at the College of Pharmacy to discuss means of fighting the ordinance passed last August prohibiting the sale at retail of any preparation containing morphin except upon the prescription of a physician. The ordinance was aimed at the sale of paregoric and cholera cure. The druggists prepared a resolution to the effect that these preparations properly labeled ought to be sold without prescription, but action on this was deferred.

For the New Montefiore Home.—At the annual meeting of the board of trustees of the Montefiore Home for Chronic Invalids it was announced that $850,000 had been subscribed toward the new buildings for this institution. It was also stated that funds sufficient to bring the amount up to $1,500,000 would soon be available. The new buildings will be erected on Gunhill Road in the Bronx, where property equivalent to 162 city lots has been purchased. The new buildings will probably accommodate 600 patients and will be ready for occupancy in about two years. The institution realized $525,000 from the sale of its old buildings.

OREGON

Personal.—Drs. Alvin F. Sether and George E. Houck have been elected aldermen of Roseburg.——Prof. Emile F. Pernot has succeeded Dr. Ralph C. Matson, Portland, as bacteriologist of the State Board of Health.——Dr. Malcolm Bronson, Hood River, was seriously injured in a fall from a cliff recently.

Hospital Notes.—Seven lots in upper Albina have been purchased by the Swedish Hospital Company which expects to erect thereon in the near future a large hospital.——At a meeting of the directors of the new Peninsula Hospital, Portland, Dr. George E. Christmas was elected vice-president; Drs. William M. Killingsworth and Charles S. Hosmer, directors.

State Sanatorium Opens.—The large brick building in Salem, formerly occupied by the State Mute School, was opened October 1, for indigent sufferers from tuberculosis. The site consists of 110 acres located about 5 miles east of Salem, and was transferred by the State Board of Health to the State Tuberculosis Commission for this purpose. The institution will accommodate fifty patients.

PENNSYLVANIA

Personal.—Drs. Lawrence Litchfield, Irwin J. Moyer, John W. Boyce, Thomas D. Davis and Percival J. Eaton have been appointed members of the examining board of the Civil Service of Pittsburg.——Dr. William A. Nealon, Pittsburg, was thrown from his automobile November 6, and sustained a slight injury to the hip.——Dr. Cornelius C. Wholey has been appointed a member of the staff of St. Francis Hospital, Pittsburg, in charge of the inebriate department.

Meeting of Northeastern Jefferson Alumni.—The Jefferson Alumni Association of Northeastern Pennsylvania held its annual meeting and banquet at Wilkes-Barre, November 10. There were sixty-five alumni present. Drs. W. M. Late Coplin and John H. Gibbon represented the faculty. The following officers were elected: president, Dr. Granville T. Matlack, Wilkes-Barre; vice-presidents, Drs. Henry M. Neale, Upper Lehigh, Daniel H. Lockard, Plymouth, and Harry W. Albertson, Scranton; secretary, Dr. J. Norman White, Scranton; and treasurer, Dr. Connell E. Murrin, Scranton.

Philadelphia

Personal.—Dr. James Tyson has been made emeritus professor of medicine, and Dr. Louis A. Duhring emeritus professor of dermatology of the University of Pennsylvania.——Dr. James E. Talley, who has been confined to the house because of injuries received in an automobile collision, is able to be out again.——Dr. Horatio C. Wood, Jr., has been appointed professor of materia medica and therapeutics in the Medico-Chirurgical College to fill the vacancy caused by the death of Dr. John V. Shoemaker.

Bequests.—Robert Steele provides in his will that his estate, amounting to $20,786, shall be placed in trust and that the income go to the widow, Amelia Steele, and following her death, the principal is to be divided among three charities. The Presbyterian Hospital is to receive $5,000 to establish a free bed in that institution, and the Presbyterian Home for Widows and Single Women, $3,000.——The will of the late James Brown provides that his estate, valued at $12,500, be placed in trust for the benefit of his widow during her life. At her death the Philadelphia Home for Incurables will receive $1,500.

Work of the Food Inspectors.—Deputy United States Marshal Myers and W. H. Jenkins, a federal food and drug inspector, seized 1,200 bottles of an alleged counterfeit "patent medicine" in the warehouse of Carbone & Co., which are said to have been purchased for the genuine from the Italian Trading Company. The medicine has had an extensive sale in the Italian section of the city, the genuine "bitters" being much used in Italy and manufactured in Milan. The food inspectors say that the Italian Trading Company recently sent representatives to the dealers in the "bitters," offering to sell them the same article at much less than they would have to pay for the imported. On this information government officials began an investigation. Samples were sent to Washington, where it was found that for grain alcohol in the genuine article, wood alcohol had been substituted and that it existed in such degree as to be extremely dangerous. On the same day 10 barrels of putrid tomato pulp were seized at the plant of the Philadelphia Pickling Co. It had been shipped here from Cambridge, Md.

Dr. Keen Operated On.—Dr. W. W. Keen has been operated on for abdominal complications and is making excellent progress toward recovery. Knowing the interest that his many friends and former pupils have in his health, THE JOURNAL secured from an authoritative source the following statement: While abroad last summer, Dr. Keen experienced some symptoms of intestinal trouble. He was examined by Dr. George A. Gibson in Edinburgh, by Dr. W. Hale White and Mr. Mummery in London, and later in Berlin by Prof. Eiselsberg of Vienna. All of them discovered an obscure tumor in the left lower abdomen. On having these facts confirmed and after consultation with his advisers, Dr. Keen decided that an abdominal section was the only positive way to determine whether the mass was a carcinoma, as seemed most likely at his age, or was non-malignant in character, and whether or not it was operable. Accordingly, as soon as possible after his return he went to Rochester, Minn., and was operated on November 9. It was found that the tumor was due to a perforating diverticulitis of the sigmoid with dense adhesions and moderate obstruction. There were two fecal stones, one of which had perforated and lay in a pocket outside the intestinal wall. It was necessary to remove a portion of the sigmoid.

VIRGINIA

Antituberculosis League Organized.—The Antituberculosis League of Petersburg was organized October 20. Dr. William F. Drewry was elected first vice-president. The principal speaker of the evening was Dr. Douglas S. Freeman, Richmond, executive secretary of the State Antituberculosis Society.

Conference on Tuberculosis.—A conference on tuberculosis will be held in Richmond, December 15 and 16. During the conference the annual business meeting of the State Antituberculosis Association will be held. At the first meeting the medical aspects of tuberculosis will be discussed. Dr. Ennion G. Williams, Richmond, state health commissioner, will preside at the first meeting. Open-air treatment will be the topic of the second meeting and tuberculosis in the cities will be that of the third session, and the fourth session will be given up to the consideration of tuberculosis, education and publicity.

WASHINGTON

Physician Leaves Bequest for Trade School.—About $100,000 is provided by the will of the late Dr. Marcel Pietrzycki, Dayton, for the building of and endowment of a trade school in Dayton.

Healers Plead Guilty.—Mrs. E. V. C. Robinson, Tacoma, a healer charged with practicing medicine without a license, is said to have pleaded guilty. Sentence was deferred.——In the case of Alexander McMasters, Spokane, charged with practicing medicine without a license, the defendant is said to have pleaded guilty, and to have been fined $50 and costs.

Personal.—Drs. Christian Quevli and Edward A. Trommald, Tacoma, have returned from Europe.——Dr. Philip Donohoo has sold his interest in the Dayton Hospital to Dr. Arthur F. Barnett, Walla Walla.——Dr. Nellie M. Baker, Urbana, Ill., has been made resident physician at a hospital in Yakima.——Dr. Frederick W. Southworth, Tacoma, who has been seriously ill, is reported to be convalescent.

GENERAL NEWS

Rush Men in Kansas and Missouri Assemble.—At the annual meeting and banquet of Rush Medical College alumni of Kansas and Missouri a permanent organization was effected. Dr. David E. Broderick, Kansas City, Mo., was elected president, and Lyman L. Uhls, Osawatomie, Kan., vice-president.

Ohio Valley Physicians Meet.—The twelfth annual meeting of the Ohio Valley Medical Association was held in Evansville, Ind., November 9 and 10. The following officers were elected: president, Dr. William D. Haines, Cincinnati; vice-presidents, Drs. Louis D. Brose, Evansville, Ind., Daniel N. Eisendrath, Chicago, and Henry R. Alburger, Bloomington, Ind., and secretary-treasurer, Dr. Benjamin L. W. Floyd, Evansville, Ind.

Cotton Belt Surgeons Elect.—The Association of Surgeons of the Cotton Belt System held its annual meeting at the general hospital of the company, Texarkana, Tex., November 1, and elected the following officers: Dr. John L. Jelks, Memphis, Tenn., president; Drs. Jesse S. Rinehart, Camden, Ark., Warren B. DeJernett, Commerce, Tex., Oscar Dowling, New Orleans, La., Homer E. Beall, Malden, Mo., and William F. Grinstead, Cairo, Ill., vice-presidents, and Dr. Harvey H. Smiley, Texarkana, Tex., secretary-treasurer (re-elected).

Meeting of American Physicians Practicing in Mexico.—The International Medical Association, composed of American physicians in practice in Mexico, met in El Paso, Texas, October 27, as guests of the El Paso County Medical Society. The following officers were elected: Dr. R. H. L. Bibb, Saltillo, Coahuila, president; Dr. J. S. Steele, Monterey, president-elect; Dr. F. W. Taube, Zacatecas, vice-president; Dr. H. S. Hodgson, Tampico, secretary-treasurer, and Dr. G. C. English, Guanajuato, censor. The next meeting will be held in Saltillo.

Occupation for Chronic Invalids and "Shut-Ins."—Passed Assistant Surgeon John M. Holt, U. S. P. H. and M. H. Service, Astoria, Ore., suggests that many chronic invalids and "shut-ins" may secure much mental rest and pleasant occupation of long hours, by becoming acquainted with the fascination of collecting, studying, sorting, and arranging postage stamps. A number of those interested in this pastime have agreed to make up Christmas packages containing stamps, albums, stickers, etc., for gratuitous distribution during the holiday season. Dr. Holt requests members of the profession all over the United States to furnish him with names and addresses of individuals who might be entertained by such remembrances.

National Meetings to Come.—The American Public Health Association will hold its next meeting in Havana, Cuba, December 4-9, 1911. The Academy of Medicine has offered its building for the general sessions and the Hotel Cevilla will be headquarters. Local physicians ask that tuberculosis be given the most prominent place on the program. It is expected that at this meeting the recently organized sociologic section and the section on sanitary engineering may be put on a substantial foundation.——The American Association for the Advancement of Science will hold its annual meeting in Minneapolis, December 27 to January 1. The majority of the meetings will be held in the halls of the University of Minnesota. One day will be given to St. Paul and the State Agriculture College.

Birth Registration Propaganda.—At the first meeting of the advisory board recently appointed by Health Commissioner Lederle, New York City, to prepare recommendations for the improvement of vital statistics in that city, a recommendation was adopted unanimously that the most important improvement which could be made consisted in the verification of the birth registration of every infant who dies under one year of age, in order to detect omissions and to cause strict enforcement of the law providing a penalty for omission to record a birth in every case thus brought to light. The census bureau is greatly interested in this movement because one of the greatest defects of American vital statistics is the entire lack of reliable rates of infant mortality due to defective birth registration.

Aim to Prolong Infant Life.—The second annual Congress of the American Association for the Study and Prevention of Infant Mortality was held in Baltimore, November 9-11. The following officers were elected: president, Prof. Charles R. Henderson, University of Chicago; president-elect, Dr. Cressy L. Wilbur, Washington, D. C.; vice-presidents, Harold McCormick, Chicago, and Dr. Henry L. Coit, Newark, N. J.; secretary, Dr. Frank S. Churchill, Chicago; executive secretary, Miss Gertrude B. Knipp, Baltimore; treasurer, Austin McLanahan, Baltimore, and executive committee, Drs. J. H. Mason Knox, Jr., Baltimore, Joseph S. Neff, Philadelphia, John S. Fulton, Baltimore, Mary Sherwood, Baltimore, and Helen C. Putnam, Providence, R. I. Chicago was chosen as the place for next meeting. Baltimore will continue to be headquarters of the national organization.

Physicians of the South in Convention.—The fourth annual meeting of the Southern Medical Association was held in Nashville, Tenn., November 8-10, under the presidency of Dr. Walter W. Crawford, Hattiesburg, Miss. The following officers were elected: president, Dr. Isadore Dyer, New Orleans; vice-presidents, Drs. William Litterer, Nashville, Tenn., William P. Adamson, Tampa, Fla., William C. Lyle, Augusta, Ga., Thomas D. Parke, Birmingham, Ala., James B. Guthrie, New Orleans, La., and Andrew G. Paine, Greenville, Miss.; and secretary-treasurer, Dr. Seale Harris, Mobile, Ala. The association adopted resolutions urging congress to establish a national department of health, and also urging the legislatures of the different southern states to pass laws compelling the inspection of school children at stated intervals. The association will meet next year in Hattiesburg, Miss.

MANILA LETTER

(From Our Regular Correspondent)

Manila, Oct. 4, 1910.

Residence in the Tropics

The effect of residence in the tropics on one's physical and mental self is a subject of not infrequent conversation in Manila. Especially is this the case, since the Americans are not altogether living up to the custom of the quiet, easy-going life, with a siesta in the middle of the day, of the average European in the tropics, nor to the Filipino motto of *manana* (to-morrow). To what extent continued residence in the tropics exerts a deleterious effect on the average individual reared in the temperate climates is a difficult matter to determine, and there is little direct evidence to confirm this supposition, which is so common a belief among the average Europeans and Americans who come to the Philippines. It is true that many women do not enjoy good health here and there are relatively a large number of children more or less anemic, and the predisposition to develop "Philippinitis" (a more or less indefinite term designed to excuse inefficiency, absentmindedness, and a general lack of ambitious endeavor) seems more or less common. But it is not known just how much all of these are due to a lack of sufficient exercise, to association, to the newness and not highly organized condition of the country and to the fact that, as middle life is approached, one becomes less and less inclined to venture into new fields and feels oneself prone to slacken one's nervous pace and perhaps to become somewhat lazy. In addition, the fact that the climate does not permit of so much strenuous exercise, is little indication that one's mental activities are in the least circumscribed. All the rush and hustle and nervousness of the larger American cities does not imply that, from a creative standpoint, the most is being accomplished. It is perhaps comparison along this line which makes life in the tropics seem slower and one feels himself apparently capable of less endeavor. It must be remembered that in the point of numbers of the white population, all Oriental tropical cities are comparatively small towns, and competition and incentive are less. In the case of the medical man, Manila (with 9,000 whites) probably furnishes as much stimulus and incentive as any town of from 40,000 to 80,000 inhabitants in the United States, and the local medical men perhaps keep as well posted in the advancement of medical science as similar men in these towns. Such considerations must be borne in mind before the tropics as a place of residence are condemned. After all it may be just as logical for the Filipino to shy at living in Chicago, from fear of developing heart disease and nervous disintegration, as it is for the American to shun life in Manila on account of the "deleterious effect of a continued residence in the tropics." Nevertheless, after long experience in both India and Egypt, many prominent British physicians long have been convinced of the validity of this supposition, and some of the Rockefeller Institute of Medical Research, on "The Prevention of the Toxic Action of Various Agencies Through the Prevention of Oxidation in the Cell."

Street and Yard Singing.—Numerous complaints have been received by the health board of the annoyance caused by singing in back yards and streets, which under the present ordinance the health department is powerless to remedy. Some of the health board officers voice the opinion that the ordinance should be so amended as to do away with the singing nuisance and also enforce quiet in the neighborhood of schools.

Personal.—Dr. Edmund L. Cocks has been appointed consulting dermatologist to Harlem Hospital.——Dr. J. Riddle Goffe has obtained from the appellate division of the supreme court the reversal of the judgment for $9,201.70 in favor of Ella H. Brown, who claimed "careless and negligent treatment." Justice Scott in presenting the opinion of the supreme court stated that Dr. Goffe was not allowed at the trial to answer a perfectly proper question as to what instructions he had given the hospital staff of physicians with reference to the care of the plaintiff.

City Druggists Protest.—Delegates from the societies representing all the retail druggists in this city met recently at the College of Pharmacy to discuss means of fighting the ordinance passed last August prohibiting the sale at retail of any preparation containing morphin except upon the prescription of a physician. The ordinance was aimed at the sale of paregoric and cholera cure. The druggists prepared a resolution to the effect that these preparations properly labeled ought to be sold without prescription, but action on this was deferred.

For the New Montefiore Home.—At the annual meeting of the board of trustees of the Montefiore Home for Chronic Invalids it was announced that $850,000 had been subscribed toward the new buildings for this institution. It was also stated that funds sufficient to bring the amount up to $1,500,000 would soon be available. The new buildings will be erected on Gunhill Road in the Bronx, where property equivalent to 162 city lots has been purchased. The new buildings will probably accommodate 600 patients and will be ready for occupancy in about two years. The institution realized $525,000 from the sale of its old buildings.

OREGON

Personal.—Drs. Alvin F. Sether and George E. Houck have been elected aldermen of Roseburg.——Prof. Emile F. Pernot has succeeded Dr. Ralph C. Matson, Portland, as bacteriologist of the State Board of Health.——Dr. Malcolm Bronson, Hood River, was seriously injured in a fall from a cliff recently.

Hospital Notes.—Seven lots in upper Albina have been purchased by the Swedish Hospital Company which expects to erect thereon in the near future a large hospital.——At a meeting of the directors of the new Peninsula Hospital, Portland, Dr. George E. Christmas was elected vice-president; Drs. William M. Killingsworth and Charles S. Hosmer, directors.

State Sanatorium Opens.—The large brick building in Salem, formerly occupied by the State Mute School, was opened October 1, for indigent sufferers from tuberculosis. The site consists of 110 acres located about 5 miles east of Salem, and was transferred by the State Board of Health to the State Tuberculosis Commission for this purpose. The institution will accommodate fifty patients.

PENNSYLVANIA

Personal.—Drs. Lawrence Litchfield, Irwin J. Moyer, John W. Boyce, Thomas D. Davis and Percival J. Eaton have been appointed members of the examining board of the Civil Service of Pittsburg.——Dr. William A. Nealon, Pittsburg, was thrown from his automobile November 6, and sustained a slight injury to the hip.——Dr. Cornelius C. Wholey has been appointed a member of the staff of St. Francis Hospital, Pittsburg, in charge of the inebriate department.

Meeting of Northeastern Jefferson Alumni.—The Jefferson Alumni Association of Northeastern Pennsylvania held its annual meeting and banquet at Wilkes-Barre, November 10. There were sixty-five alumni present. Drs. W. M. Late Coplin and John H. Gibbon represented the faculty. The following officers were elected: president, Dr. Granville T. Matlack, Wilkes-Barre; vice-presidents, Drs. Henry M. Neale, Upper Lehigh, Daniel H. Lockard, Plymouth, and Harry W. Albertson, Scranton; secretary, Dr. J. Norman White, Scranton; and treasurer, Dr. Connell E. Murrin, Scranton.

Philadelphia

Personal.—Dr. James Tyson has been made emeritus professor of medicine, and Dr. Louis A. Duhring emeritus professor of dermatology of the University of Pennsylvania.——Dr. James E. Talley, who has been confined to the house because of injuries received in an automobile collision, is able to be out again.——Dr. Horatio C. Wood, Jr., has been appointed professor of materia medica and therapeutics in the Medico-Chirurgical College to fill the vacancy caused by the death of Dr. John V. Shoemaker.

Bequests.—Robert Steele provides in his will that his estate, amounting to $20,786, shall be placed in trust and that the income go to the widow, Amelia Steele, and following her death, the principal is to be divided among three charities. The Presbyterian Hospital is to receive $5,000 to establish a free bed in that institution, and the Presbyterian Home for Widows and Single Women, $3,000.——The will of the late James Brown provides that his estate, valued at $12,500, be placed in trust for the benefit of his widow during her life. At her death the Philadelphia Home for Incurables will receive $1,500.

Work of the Food Inspectors.—Deputy United States Marshal Myers and W. H. Jenkins, a federal food and drug inspector, seized 1,200 bottles of an alleged counterfeit "patent medicine" in the warehouse of Carbone & Co., which are said to have been purchased for the genuine from the Italian Trading Company. The medicine has had an extensive sale in the Italian section of the city, the genuine "bitters" being much used in Italy and manufactured in Milan. The food inspectors say that the Italian Trading Company recently sent representatives to the dealers in the "bitters," offering to sell them the same article at much less than they would have to pay for the imported. On this information government officials began an investigation. Samples were sent to Washington, where it was found that for grain alcohol in the genuine article, wood alcohol had been substituted and that it existed in such degree as to be extremely dangerous. On the same day 10 barrels of putrid tomato pulp were seized at the plant of the Philadelphia Pickling Co. It had been shipped here from Cambridge, Md.

Dr. Keen Operated On.—Dr. W. W. Keen has been operated on for abdominal complications and is making excellent progress toward recovery. Knowing the interest that his many friends and former pupils have in his health, The Journal secured from an authoritative source the following statement: While abroad last summer, Dr. Keen experienced some symptoms of intestinal trouble. He was examined by Dr. George A. Gibson in Edinburgh, by Dr. W. Hale White and Mr. Mummery in London, and later in Berlin by Prof. Eiselsberg of Vienna. All of them discovered an obscure tumor in the left lower abdomen. On having these facts confirmed and after consultation with his advisers, Dr. Keen decided that an abdominal section was the only positive way to determine whether the mass was a carcinoma, as seemed most likely at his age, or was non-malignant in character, and whether or not it was operable. Accordingly, as soon as possible after his return he went to Rochester, Minn., and was operated on November 9. It was found that the tumor was due to a perforating diverticulitis of the sigmoid with dense adhesions and moderate obstruction. There were two fecal stones, one of which had perforated and lay in a pocket outside the intestinal wall. It was necessary to remove a portion of the sigmoid.

VIRGINIA

Antituberculosis League Organized.—The Antituberculosis League of Petersburg was organized October 20. Dr. William F. Drewry was elected first vice-president. The principal speaker of the evening was Dr. Douglas S. Freeman, Richmond, executive secretary of the State Antituberculosis Society.

Conference on Tuberculosis.—A conference on tuberculosis will be held in Richmond, December 15 and 16. During the conference the annual business meeting of the State Antituberculosis Association will be held. At the first meeting the medical aspects of tuberculosis will be discussed. Dr. Ennion G. Williams, Richmond, state health commissioner, will preside at the first meeting. Open-air treatment will be the topic of the second meeting and tuberculosis in the cities will be that of the third session, and the fourth session will be given up to the consideration of tuberculosis, education and publicity.

WASHINGTON

Physician Leaves Bequest for Trade School.—About $100,000 is provided by the will of the late Dr. Marcel Pietrzycki, Dayton, for the building of and endowment of a trade school in Dayton.

Healers Plead Guilty.—Mrs E V. C Robinson, Tacoma, a healer charged with practicing medicine without a license, is said to have pleaded guilty. Sentence was deferred ——In the case of Alexander McMasters, Spokane, charged with practicing medicine without a license, the defendant is said to have pleaded guilty, and to have been fined $50 and costs

Personal—Drs Christian Quevli and Edward A Trommald, Tacoma, have returned from Europe ——Dr. Philip Donohoo has sold his interest in the Dayton Hospital to Dr. Arthur F. Barnett, Walla Walla ——Dr Nellie M Baker, Urbana, Ill, has been made resident physician at a hospital in Yakima. ——Dr Frederick W Southworth, Tacoma, who has been seriously ill, is reported to be convalescent.

MANILA LETTER

(From Our Regular Correspondent)

Manila, Oct. 4, 1910

Residence in the Tropics

The effect of residence in the tropics on one's physical and mental self is a subject of not infrequent conversation in Manila Especially is this the case, since the Americans are not altogether living up to the custom of the quiet, easy going life, with a siesta in the middle of the day, of the average European in the tropics, nor to the Filipino motto of *manana* (to morrow) To what extent continued residence in the tropics exerts a deleterious effect on the average individual reared in the temperate climates is a difficult matter to determine, and there is little direct evidence to confirm this supposition, which is so common a belief among the average Europeans and Americans who come to the Philippines It is true that many women do not enjoy good health here and there are relatively a large number of children more or less anemic, and the predisposition to develop "Philippinitis" (a more or less indefinite term designed to excuse inefficiency, absentmindedness, and a general lack of ambitious endeavor) seems more or less common But it is not known just how much all of these are due to a lack of sufficient exercise to association, to the newness and not highly organized condition of the country and to the fact that, as middle life is approached, one becomes less and less inclined to venture into new fields and feels oneself prone to slacken one's nervous pace and perhaps to become somewhat lazy In addition, the fact that the climate does not permit of so much strenuous exercise, is little indication that one's mental activities are in the least circumscribed All the rush and hustle and nervousness of the larger American cities does not imply that, from a creative standpoint, the most is being accomplished It is perhaps comparison along this line which makes life in the tropics seem slower and one feels himself apparently capable of less endeavor It must be remembered that in the point of numbers of the white population, all Oriental tropical cities are comparatively small towns, and competition and incentive are less In the case of the medical man, Manila (with 9,000 whites) probably furnishes as much stimulus and incentive as any town of from 40 000 to 80 000 inhabitants in the United States, and the local medical men perhaps keep as well posted in the advancement of medical science as similar men in these towns Such considerations must be borne in mind before the tropics as a place of residence are condemned After all it may be just as logical for the Filipino to shy at living in Chicago, from fear of developing heart disease and nervous disintegration, as it is for the American to shun life in Manila on account of the "deleterious effect of a continued residence in the tropics" Nevertheless, after long experience in both India and Egypt, many prominent British physicians long have been convinced of the validity of this supposition, and some investigation to determine the underlying cause has been made here in the Philippines. Dr. W. E. Musgrave, professor of clinical medicine in the Philippine Medical School and the American physician of longest residence in the Philippines, sums up his convictions on the subject as follows: "The lot of one transiently present in the Philippines is not a particularly hazardous one. Such a person's chances of avoiding infectious diseases and otherwise of maintaining good health are equal to his chances in most countries of the world, and are far better than they are in any other tropical far eastern or Asiatic country. However, prolonged or permanent residence in these islands or in any other tropical country certainly produces deleterious effects on people, be they of native or foreign birth. The usually accepted statement that the tropics exert any especially bad influence on the foreigner from which the native escapes is, so far as my observations go, not borne out by the facts. But it is a fact that prolonged residence produces, or is intimately connected with, certain disease conditions which are not particular to any race, nationality or complexion, and these irregularities are cured only by at least a temporary change of climate and surroundings. In the case of natives of the tropics, generations of residence has produced, to say the least, a more or less uniform dwarfing of energy and efficiency; and with this have developed altered standards of measurements in which the inaccuracy of the normal is only noticed by comparison. This comparison may be made with foreigners or, still better, and the results are just as striking, in born natives of the tropics who have been removed to temperate climates." The principal change is thought to be a tendency toward a condition of general sluggishness of mind and body. But "in the case of children the problem is a more important one. . . . Among medical men of experience in the tropics I believe the opinion is a very general one that children should not reside in the tropics during the formative period of years. The exact etiologic factor in these conditions is not known; heat, the actinic rays of the sun, and many other agents have been incriminated, but it is probable that the cause is really broader and more complex and has to do with the peculiar arrangement of the natural laws governing health and disease."

At the Bureau of Science a physical analysis has been made of the tropical sunlight and a determination of the total yearly and the average daily amount of sunlight of different qualities is still in progress. After completing this study it is hoped to get data of this kind from various countries in the temperate climate for comparison. The question of the so-called actinic rays of the sun will probably be greatly elucidated by such investigations.

LONDON LETTER

(From Our Regular Correspondent)

London, Nov. 5, 1910.

Plague in England

In a previous letter to The Journal [November 5, p. 1658] cases of plague in ships which arrived in the Thames have been reported. It has now been found that plague prevails extensively among rats in part of Suffolk, one of the eastern counties of England, and that a few cases have occurred in man. Hares and rabbits also have been attacked. The outbreak seems to be due to the landing of an infected rat or rats from one of the many grain-vessels which enter the river Orwell from plague-infected countries. The immense overseas trade of this country causes wonder that such an event has not occurred previously. Improved sanitation has much diminished the danger, however. There has been no epidemic of plague in this country since the great plague of the reign of Charles II, so graphically described by Defoe. The greatest vigilance is practiced in all our ports to exclude plague-infected rats. Whenever dead rats are discovered in a ship the vessel is disinfected and the holds are cleared out; in addition the docks are overhauled at intervals. Last year many rats affected with plague died in a warehouse in one of the London docks, but the disease was completely controlled by the sanitary authorities. The same thing has occurred in other ports on a small scale. In the infected district of Suffolk (about 20,000 acres) a most energetic campaign is being carried on for the destruction of rats by the health authorities and the inhabitants, and many thousands of rats are being killed daily by rat-catchers, dogs, guns, ferrets and poison. A cat, which was shot and buried because it was looking ill, was unearthed by the health authorities and bacteriologic examination made, which showed the presence of plague bacilli. So far only four cases have occurred in man. At the scattered little village of Freston 4 miles from Ipswich, the capital of the county, four persons died from a mysterious illness. The outbreak began in a child who was fondling a pet cat before her seizure. She died on the fourth day with symptoms of very acute septic pneumonia. On the day after her burial her mother, who had nursed her, was taken ill with similar pneumonic symptoms and died after forty-eight hours. Then the second patient's husband and a woman who nursed her were attacked and died on the fourth day. Before the death of the mother her physician entertained suspicions as to the nature of the disease and had a bacteriologic examination made of her blood and of expectoration which revealed the plague bacillus.

Poster Campaign Against Tuberculosis

A poster campaign against tuberculosis has been begun in the United Kingdom by the National Association for the Prevention of Consumption. On the boardings are displayed large posters measuring 10 by 7½ feet, on which are printed the main facts in regard to the disease and an appeal for funds to stamp it out. The precautionary measures to prevent attacks and the course to be followed in the earliest stages are stated.

The New Building for the Royal Society of Medicine

The Royal Society of Medicine, which, as stated in previous letters to The Journal, has been formed by the amalgamation of nearly all the medical societies of the metropolis and is therefore in a way the largest medical society, is erecting a new building into which it will move when completed, at the Cavendish Square end of Wimpole Street. The cost will be upwards of $150,000. Toward this the medical profession has subscribed $12,000 and an appeal is now being made to the public for subscriptions through a committee of which the Lord Mayor of London is chairman. He points out that for many years the society has been engaged in work of the utmost value not only to the state but to mankind, and that its fellows have not spared time, trouble, or expense in carrying out a really national and philanthropic work, which is not of the slightest personal advantage to the individual workers. If no less than $130,000 is contributed from without the society will be able to provide all the income necessary for continuing and enlarging its beneficent labors. It has now 3,200 fellows and members and a library of nearly 100,000 volumes. It was founded in 1805 under the name of "The Royal Medical and Chirurgical Society."

Divorce and Insanity

A royal commission appointed by the government to investigate the question of divorce is now sitting. The bearing of insanity on divorce was the subject on which evidence was taken at the last sitting. The British Medical Association appointed a number of eminent alienists to give evidence on the recognition of insanity as a ground for divorce. These were Dr. Smith Clouston, lecturer on mental diseases, Edinburgh University; Dr. Robert Jones, lecturer on mental diseases, St. Bartholomew's Hospital, and Dr. T. R. Hyslop, resident physician, Bethlehem Hospital. Dr. Smith Clouston was of opinion that there were certain forms of mental diseases for which the law should be so altered as to redress the present hardships to husbands and wives, and especially make provision for the better guardianship of children and prevent the birth of children with an undue liability to mental disease. Divorce should be applicable only to persons proved to labor under incurable mental disease, except in certain cases. One of the main proofs of incurability was the length of time during which a patient had suffered continuously from mental disease. In very few cases would Dr. Clouston feel justified in giving an opinion that a patient was incurable within twelve months of the onset of the disease, whatever the symptoms. In most cases no divorce proceedings should be allowed within from three to five years after the commencement of the mental disease. Dr. Clouston absolutely disapproved of the marriage of epileptics on medical and eugenic grounds. The disease was hereditary in a high degree and epileptics almost certainly had insane, epileptic, and idiotic progeny. If marriage was contracted a remedy should be possible by means of divorce. The congenitally feeble-minded, as distinguished from imbeciles and idiots, frequently married and a large number of the females produced illegitimate children. Divorce should always be obtainable and the most stringent means should be taken to prevent pregnancy in such feeble-minded young women. They were the source of vast amount of insanity, crime and pauperism. In alcoholic dementia divorce should always be applicable, because not only was the condition incurable but the subjects had brought it on by their own acts Dipsomaniacs should also come under any alteration in the divorce law, but he would give them ten years in which to recover. At a subsequent sitting Sir James Crichton Browne has stated that though the majority of doctors would be in agreement with these witnesses, a strong body of opinion in the profession holds a different view The proposal that insanity of any kind should be a ground for divorce seemed to him highly objectionable It would encourage imprudence in marriage, conduce to instability of the matrimonial state, and further impair the sanctity of family life Insanity was simply a bodily disease manifesting itself by a mental derangement and if it was to be recognized as a sufficient reason for divorce he did not see why other diseases should not be recognized also It was suggested that only incurable insanity would be a ground for divorce, but what was to be the test? Nothing had struck him more in his experience as a commissioner in lunacy than the way in which complete recovery occasionally took place in cases of insanity regarded by experts as utterly hopeless

An Ideal Meeting Room

There has been fitted up at the rooms of the Society of Medical Officers of Health, London, what is said by the society to be the most hygienic meeting place in London The room which can accommodate 150 persons, has been designed to demonstrate the working of ventilating, warming and lighting patents, and also to show the proper arrangement of a hygienic assembly room By means of levers the temperature can be raised or lowered immediately The air is drawn from outside by means of electric fans and carried along a shaft to radiators which warm it to the desired temperature It is then forced along another shaft to the sides of the room and diffused by a patent diffusing apparatus Meanwhile a powerful electric fan extracts the foul air Artificial light is supplied by gas, an enclosed globe like an electric arc lamp being suspended from the center of the ceiling, and governed by a patent vacuum switch which connects it with the by pass It is claimed that, however dense the fog outside, the air in the room will remain perfectly clear and pure In recognition of his services in connection with the Panama Canal sanitation work, the society has decided to elect Mr. Roosevelt a fellow.

Seventeenth International Congress of Medicine

The seventeenth International Congress of Medicine will be held in London in the summer of 1913 At a meeting of the General Medical Council, Sir Thomas Barlow, president of the Royal College of Physicians, was elected president of the congress, Mr G H Makins, treasurer, and Dr. Herringham, secretary An influential organizing committee representative of all the medical bodies in the country was also appointed It was resolved that distinguished laymen should be invited to associate themselves with the work of the congress The date led to considerable discussion. It was proposed to hold it at some date from July 29 to August 6, but as the British Medical Association always meets at that time it was decided to leave the president and executive officers to settle the date and to give them liberty to confer with the officers of the British Medical Association

The Right to Efficient Ventilation at Sea

The right to efficient ventilation at sea has been established in the courts by the following important case Two passengers returning from South Africa by the Union Castle Mail Steamship Co complained that their cabin was unventilated and paid $18 to occupy another cabin as "a cabin without a fan was quite intolerable" The company in their booklet stated that a complete system of ventilation had been adopted and that electricity was brought to bear on the cabins, saloons etc, by a large number of electric fans The judge said that anyone reading the booklet would think that all the cabins had electric fans As the discarded cabin had no fan he gave judgment for the passengers and ordered the company to return the money paid for the change of cabins

PARIS LETTER

(*From Our Regular Correspondent*)

PARIS, Nov 4, 1910

Statistics of the Population of France

The *Journal Officiel* has just published the statistics of the population of France for the first six months of 1910 The results, without being satisfactory, are less unfavorable than those of the corresponding six months of the previous year While in the first six months of 1909 an excess of 28 203 deaths was recorded, during the first six months of 1910 there was an excess of 21,189 births The births have not increased appreciably The birth rate still remains low 399,669 in 1910 in place of 398,710 in 1909 But the deaths have decreased considerably. 378,480 instead of 426,913 As for marriages, their number has remained stationary 156,761 in place of 156,258, and the divorces continue to increase 6 383 against 6,118 As for the Department of Seine, during the first six months of the present year, 37,319 births, 38,567 deaths, 20,389 marriages and 1,365 divorces have been recorded

Death of M. Henri Dunant

Hardly two and a half months have elapsed since the death of Miss Florence Nightingale, the celebrated organizer of the hospital and ambulance service of the Crimean war, and now Henri Dunant one of the founders of the Red Cross, has just died Inspired by the example of Florence Nightingale in 1859, during the war with Italy, he conceived the idea of organizing, by private initiative, an international service of aid to the wounded, which was rendered necessary by the inadequacy of the military ambulance service Born in 1828, Henri Dunant was 31 years old when the accidents of a pleasure journey brought him on the battle field of Solferino, strewn with dead and wounded, who were not picked up or cared for until two or three days had passed The brochure which Dunant published on this subject, in 1862 ("Un Souvenir de Solferino"), created an extraordinary sensation, and it was in great part owing to the propaganda of this apostle of charity that there was held in Geneva, October 26 29, 1863, the celebrated international conference which had for results the meeting of the diplomatic congress of August 8 22, 1864, and the conclusion of the convention of Geneva for the improvement of the condition of soldiers wounded during a campaign In 1867, Henri Dunant lost his fortune, and for twenty five years led a life of restriction and privation In 1901 he was awarded one of the Nobel prizes He died at Heiden, Appenzell Switzerland, on the shores of Lake Constance where he had lived for several years

Conference on Social Hygiene

The sixth annual meeting of the Alliance d'hygiène sociale, which has just been held at Marseilles, unanimously passed a resolution for the prohibition of the manufacture and sale of absinthe and the limitation of the number of licenses The assembly, moreover, adopted the following resolutions· (1) that all bills for the protection of children should be submitted to the parliamentary commission of hygiene, (2) that it was most desirable to pass a law against depopulation, for the protection of maternity and early childhood, and the awarding of aid to large families

Pharmacist Condemned for Fraud

A pharmacist has been condemned by the court of Amiens, Somme to pay damages to the *syndicat* of the pharmacists of the region for having sold syrup of ipecac to which he had added tartar emetic The delivery, under the name of syrup of ipecac, of another preparation, the court held. constituted fraud Moreover, the court recognized the fact that a professional association (*syndicat*) of pharmacists legally organized to prevent any injury to the moral interests of pharmacy had an indisputable moral interest in upholding its standards which justified its intervention as civil party to the suit and the awarding of damages

Clergymen in the Campaign Against Tuberculosis

The Oeuvre de la tuberculose humaine, which has organized antituberculosis leagues among all classes (teachers postal employees, members of benefit societies agents of the railways, public functionaries, etc), has just written to French clergymen of all faiths, asking them to devote one or two sermons annually to the cause represented by the society In each parish the inhabitants would then be initiated in the principles of hygiene and of sanitary prophylaxis

Bacillus Carriers

M Chéron, assistant secretary of the navy, has addressed to the maritime prefects a circular on the prophylaxis of the various forms of typhoidal infections and the means of contagion The circular calls the attention of the sanitary service to the necessity of isolating bacillus carriers, and recommends that sailors be informed of the daily dangers which threaten them in the places that they are required to frequent M Chéron requires that he be informed every six months of the measures taken for the application of his instructions and the results obtained

Nursing-Bottles with Tubes

Dr. Savary, inspector of public charities, draws attention to a regrettable omission in the law recently passed (The Journal Oct. 1, 1910, p. 1211) which prohibits the putting on sale, the exhibition and importation of nursing-bottles with tubes. Their use, however, has not been expressly prohibited, so that the inspectors of the public charities have no recourse against the nurses who persist in the old ways. The pharmacists have ceased to sell such apparatus, but the nurses who want to use the tube nursing-bottles because of the freedom which it leaves them make the apparatus themselves. A medical inspector, on a tour of inspection, saw several nursing-bottles with tubes made by nurses, and once found two babies, one of which had hereditary syphilis, in the same cradle sucking from a nursing-bottle with two tubes which the nurse had arranged. The nipples were frequently exchanged. Such facts show how important it is to amend the present law.

Death of Dr. Armand Trousseau

Dr. Armand Trousseau, head physician of the clinic of the Hospice des Quinze-Vingts and of the Rothschild ophthalmologic institution, has just died, aged 54, from an automobile accident. Dr. Trousseau was born in Paris in 1856. He was formerly an intern of the hospitals and specialized from the beginning of his career in diseases of the eye. In 1886 he entered the clinic of the Hospice des Quinze-Vingts, becoming head physician three years later. Having been called to attend Baron Adolphe de Rothschild, he advised the great banker to found the institution which bears his name. Baron de Rothschild in his will appointed Dr. Trousseau to direct this foundation. Dr. Trousseau was the grandson of the famous clinician who died in 1867.

Diminution of Cases of Hydrophobia

Dr. Maurice Letulle, *agrégé* professor at the Paris medical college, during the last session of the Council of Hygiene and Salubrity, made a report on hydrophobia during the period from 1904 to 1909, setting forth the success obtained in the prophylaxis of rabies. While in Paris and the Department of the Seine, the number of biting animals remains about the same from one year to another, the proportion of animals in which hydrophobia has been recognized is continually and rapidly decreasing. While 474 animals were affected with hydrophobia in 1902, there were only 172 in 1904, 120 in 1905, 74 in 1906, 46 in 1907, 55 in 1908, and 13 in 1909. Of all animals the one most to be feared is the dog. In 1909, of 1,903 biting animals there were 833 dogs, 247 horses, 6 cats and 7 miscellaneous. Cases of hydrophobia are more frequent in the suburbs than in Paris, since in the six years studied, Paris has had only 211 cases, while the suburbs have had 249. It is at the Pasteur Institute, especially, that the progress of the prophylaxis of hydrophobia can be estimated. From 1904 to 1909 the number of persons bitten in the Department of the Seine amounted to 7,576, of whom 307 were bitten by animals known to be mad (183 in the suburbs and 124 in Paris). The number bitten by rabid animals was about 87 in 1904, and about 90 in 1905. It has progressively decreased to 65 in 1906, 35 in 1907, 24 in 1908, and 6 in 1909. Out of the 1,069 individuals cared for since 1904, fortunately there has been only one fatal case, which occurred in 1904. This was the last victim of the scourge in the region of Paris. Within six years only two cases of hydrophobia have been found in more than 68,000 stray dogs captured at the Fourrière (establishment where stray and abandoned dogs are received). Previously there was an average of 26 a year (155 from 1898 to 1903). Human hydrophobia, which caused twenty-two deaths as late as 1885, and twelve in 1901, has caused none for five years.

To what is this progressive disappearance of endemic rabies in Paris due? Dr. Letulle does not hesitate to attribute it to administrative measures. The capture of stray dogs in Paris has rendered valuable service because it has been carried on with great zeal and strictness. According as the pursuit is carried on methodically and without cessation, or relaxes for one reason or another, hydrophobia diminishes, seems to become extinguished, or revives and multiplies the number of its victims. It is necessary, then, to persist without slackening in the annual capture of twelve or fourteen thousa stray dogs in Paris if we wish to extirpate hydrophobia.

The Value of Tuberculin Therapy

The treatment of tuberculosis by tuberculin, which has bee the subject of many recent investigations in Germany, has, u to the present, found few advocates among French physicia The discussion held at the Congress of Internal Medicine proves that a change in this respect is now taking place. Dr. Louis Rénon, physician of the hospitals of Paris, declares that tuberculin, while constituting only a partial treatment of tuberculosis, still exercises an undeniable action in certain cases, notably in incipient tuberculosis and in torpid tuberculosis already treated or ameliorated by the usual medications and climate. Relative absence of fever is a necessary condition for the use of tuberculin in the patients not in hospitals. All tuberculins may be used on condition that one begins with relatively weak doses (1/500 mg.), increasing to 1/20 mg. It is necessary to avoid all apparent local or general reaction and to modify the injections according to the data furnished by the clinical examination. Dr. Bauer of Neufchâtel also recommends, in using tuberculin therapy, the greatest care in the observation of the individual reactions which cannot be foreseen. Dr. Mantoux of Cannes drew attention to the favorable results from tuberculin therapy in tuberculous lesions of the urinary organs; 48 per cent. of the patients improved and 33 per cent. were cured. Tuberculin therapy ought to be employed in cases in which the lesions are limited to the bladder in bilateral or unilateral renal tuberculosis at the beginning. Prof. J. Teissier of Lyons observed a very serious case of renal tuberculosis with numerous Koch bacilli in the urine in which tuberculin therapy led not only to disappearance of all the clinical phenomena and the improvement of the general condition, but also to the complete disappearance of the tubercle bacilli in the urine.

A New Diagnostic Sign in Pleuropulmonary Affections

On October 18, Dr. Hirtz, physician at the Necker Hospital, reported at the Académie de Médecine a diagnostic sign of some affections of the pleura or the lungs obtained by the percussion of the thorax under sustained inspiration. When the patient breathes normally percussion shows a dulness at the base of one or both lungs. One thinks of double or single pleurisy, but after making the patient take a forced and sustained inspiration, one percusses the thorax again, and finds that the point which seemed dull has become sonorous. It is not then an effusion; it is the pulmonary element which is incriminated. This sign permits the differentiation, without exploratory puncture, of congestion and pulmonary edema or spleno-pneumonia with pleural effusion. It makes it possible to say, then, in the course of pleurisy, if liquid is present or not. In short, certain apparently tuberculous congestions of the apex of the lung, in subjects of Bright's disease or heart disease, may receive their true interpretation through this new sign. In such case everything conspires to lead the clinician into error: the general condition of the patient, some anterior hemoptyses, and dyspnea; and in ordinary respiration, the dulness of the apices of the lungs appears incontestable and inclines the diagnosis toward tuberculosis; but as soon as percussion, under forced and sustained inspiration, is used, the tone becomes resonant and the error is avoided.

The Number of Fetal Heart-Beats and the Sex of the Child

At the Congrès de gynécologie, d' obstétrique et de pédiatrie, held at Toulouse, Dr. Fieux, *agrégé* at the Bordeaux medical college, communicated the results of investigations which he has made on fifty women, to find out what relation the number of the fetal heart-beats bears to the sex of the child. He presents his results in two tables. In the first, the fetal heart-beats never exceed 136; in the second they never fall below this figure. The first table gives seventeen boys (or 60 per cent.) and eleven girls (or 40 per cent.) The second table gives fifteen girls (or 68 per cent.) and seven boys (or 32 per cent.). Among the subjects with very high rhythms (160-180) girls are found almost exclusively. It is necessary to make the mother rest for some minutes before practicing auscultation and to auscultate the fetus during a period of calm. If these rules are observed the variations between the results of the various auscultations of one fetus are very slight, and the figure remains almost the same from the moment when the heart-beats are clearly perceptible to the end of the pregnancy.

Dangers of Poppy Decoctions

ploy decoctions of the poppy-head as a sopori-
tain parts of France, especially in the
ille, the physician who had made out
infant of 4 months refused to permit
because he attributed the death
The grandmother confessed that

within 8 days the child had absorbed an infusion of three poppy heads in 1 liter (about a quart) of water. The autopsy showed no disease which might account for the death, but did disclose some signs of habitual opium intoxication, and on chemical analysis the viscera were found to contain a toxic quantity of morphin. In reporting the case at the last session of the Société de médecine légale, Dr. Dutilleul and M. Bonn, a chemist, remarked that it was strange that while morphin and the other alkaloids of opium are among the poisonous substances which the pharmacist can deliver only on receipt of a medical prescription, the substance from which these alkaloids are obtained is freely sold, not only by pharmacists, but by grocers, seedsmen and herb dealers. A check on the sale of poppy-heads would prevent the death of many children each year.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Oct. 28, 1910.

Personal

Professor Brandenburg, director of the internal department of the district hospital of Grosslichterfeld, has been appointed head physician of the second internal department of the Rudolf Virchow hospital. He is the successor of Professor L. Kuttner, who, as previously announced, has been appointed director of the department.

Professor Kossel, director of the physiologic institute at Heidelberg, has been awarded the Nobel prize in medicine for this year. Kossel, a pupil of Dubois Reymond, has especially distinguished himself by his valuable investigations of the nuclein metabolism in the cells.

Professor Zangemeister, a pupil of Professor Winter of Königsberg, has been called to Marburg as director of the gynecologic clinic to succeed Professor Stöckel.——Professor v. Leube of Würzburg celebrated the completion of his twenty-fifth year as regular professor, October 31.

Semicentennial of the Berlin Medical Society

Oct. 26 the Berliner medizinische Gesellschaft celebrated its semicentennial. The memorial meeting was of peculiar importance, as this society is not only the largest medical association in Berlin, but also one of the most noted and largest in Germany and can look back on a notable past. The society was formed by the union of two Berlin societies. The older of these was founded in 1844 as a society for scientific medicine, and the younger was the Verein Berliner Aerzte, founded in 1858. In order to obviate any difficulties arising from the union of the two societies, which took place in 1860, Rudolf Virchow resigned his position as president of the society for scientific medicine, in favor of Albrecht v. Gräfe, the president of the other society. The Berlin Medical Society, in spite of the separation from it of numerous special associations, of which that founded by v. Leyden as the Verein für innere Medizin was the first, has still remained the central point of scientific medical activity in Berlin, and almost every Berlin physician considers it his duty to belong to it, so that at present it has more than 1,600 members. As a result of the participation of the university teachers, the scientific proceedings are always valuable and a number of important discoveries have been presented here for the first time. As successors of v. Gräfe, Bernhardt von Langenbeck, Rudolf Virchow, Ernst v. Bergmann, and finally H. Senator have held the office of president. Robert Koch, Helmholtz and Pasteur were made honorary members, a distinction which has seldom been bestowed. On the occasion of the semicentennial the number of honorary members was considerably increased, including in addition to two living members of the society, two physicians practicing in Berlin, Professor Waldeyer and the surgeon general of the Prussian army, v. Schjerning, Naunyn (Baden-Baden), Exner and Fuchs (Vienna), Golgi, Armauer-Hansen (Christiania), Abraham Jacobi (New York), Fr. Koranyi (Budapest), Keen (Philadelphia), Kitasato (Tokio), Laveran (Paris), Lépine (Lyons), Lister, Murri (Bologna), Pawlow (St. Petersburg), Ramon y Cajal (Madrid), Retzius (Stockholm), Salomonsen (Copenhagen), and Röntgen (Munich). Senator was elected honorary president. On the festival day it was announced that so far $15,000 (63,000 marks) had been subscribed by the members for the building of the projected Virchow House which is to be the special home of the society. The widow of Virchow on the same occasion announced that she would make over to the new building the private collections and valuable memorials of Virchow.

Statistics of Hydrophobia for Prussia for 1909

In 1909 there were 406 injuries of human beings in Prussia by rabid animals or those suspected to be rabid. The greatest number occurred as formerly in the eastern provinces, in those districts which touch the Russian boundary to the greatest extent. The wounds were inflicted mostly by dogs, but to far less extent by cats, horses, cattle and deer. Nineteen persons received wounds while tending two hydrophobic patients; 252 of the wounds were inflicted by animals which were certainly rabid; 374 of the wounded received the Pasteur inoculation in Berlin and Breslau. Of the 374 inoculated, eight died (2.13 per cent.). Of the thirty-two who were not inoculated, two died (6.25 per cent.); the latter were included among the twenty-two persons who were bitten by animals certainly rabid, which gives a mortality of 9.1 per cent.

Communication of Typhoid by Butter and Cheese

Professor Gaffky, director of the institute for infectious diseases, in a report to the minister of education, states that there are no published accounts of the transmission of typhoid by butter and cheese. Theoretically it may be said that according to previously published investigations, typhoid bacilli may remain viable in artificially infected butter from 21 to 27 days and that they pass for the most part into the cream that is used for butter when separated by the centrifuge. In the curd obtained from milk (cheese made from sweet milk), the bacilli added to the milk are found, but they are rapidly killed by the acids that form in the curd, so that they cannot be demonstrated after the third day. Gaffky therefore comes to the conclusion that butter made from sour cream, the curds from sour milk, and matured cheese are not likely to communicate typhoid. To avoid communication by butter from sweet cream and cheese made from the same material, pasteurization of the milk is to be recommended, since a temperature of 60 C. is sufficient to kill the typhoid bacilli in milk and does not affect the preparation or the taste of the products made from it.

Carbohydrates in the Diet of Children

At the last session of the German pediatric society, Professor Langstein, head physician of the Augusta Victoria institute for prevention of infant mortality, made an interesting address on the rôle of carbohydrates in infant-feeding. The nutrition of the healthy child is to be sharply distinguished from that of the sick child. For the improvement of artificial nutrition, it is necessary to determine the healthy infant's absolute requirement of carbohydrates. For the artificial nutrition of the healthy child, no other viewpoint is appropriate except to furnish in a volume which as nearly as possible corresponds to the natural, as much nourishment as the law of energy requires for infants. The natural flour suffices for the nutrition of healthy infants and it is not necessary to employ flour prepared for infants. Overfeeding with sugar, even if there are no alarming symptoms referable to the gastro-intestinal tract, appears to be capable of leading to severe injury of the child's organism. Exclusive nourishment with flour, if long continued, may lead to severe disturbances of nutrition. Disproportionate nourishment with flour appears to lead to a chemical degeneration of the organism that involves a loss of immunity. In the proper amount the carbohydrates are indispensable for the treatment of disturbances of nutrition in infants. The enrichment of the diet by carbohydrates is of the greatest importance in the so-called milk-diet diseases (*Milchnährschaden*). The importance of carbohydrates in these cases is due to the fact that they hinder the formation of soaps in the intestine. The various carbohydrates behave quite differently in reference to this power. Milk-sugar is the carbohydrate which is least adapted to the child whose nutrition is disturbed. Cane sugar appears more efficient in these cases. The best combination seems to be that of flour and malted preparations. A complete loss of tolerance for carbohydrates is incompatible with the continuance of life.

Statistics of Physicians in the German Empire

In the period from 1885-1907, while the population of the German Empire increased 32 per cent. (from 46,700,000 to 61,700,000), the number of physicians increased 102 per cent. (from 15,764 to 31,864). The percentage increase of physicians is thus more than three times as great as that of t
population. In 1885 the ratio was 3.4 phy 10,0
inhabitants; in 1907 it was 5.2. Professiona
ished for this reason, have been still more
social legislation which has included a large
patients among the insured.

Nursing-Bottles with Tubes

Dr. Savary, inspector of public charities, draws attention to a regrettable omission in the law recently passed (The Journal Oct. 1, 1910, p. 1211) which prohibits [illegible] on sale, the exhibition and importation of [illegible] tubes. Their use, however, has not been expressly prohibited, so that the inspectors of the public charities have no recourse against the nurses who persist in the old ways. The pharmacists have ceased to sell such apparatus, but the nurses who want to use the tube nursing-bottles because of the freedom which it leaves them make the apparatus themselves. A medical inspector, on a tour of inspection, saw several nursing-bottles with tubes made by nurses, and once found two babies, one of which had hereditary syphilis, in the same cradle sucking from a nursing-bottle with two tubes which the nurse had arranged. The nipples were frequently exchanged. Such facts show how important it is to amend the present law.

Death of Dr. Armand Trousseau

Dr. Armand Trousseau, head physician of the clinic of the Hospice des Quinze-Vingts and of the Rothschild ophthalmologic institution, has just died, aged 54, from an automobile accident. Dr. Trousseau was born in Paris in 1856. He was formerly an intern of the hospitals and specialized from the beginning of his career in diseases of the eye. In 1886 he entered the clinic of the Hospice des Quinze-Vingts, becoming head physician three years later. Having been called to attend Baron Adolphe de Rothschild, he advised the great banker to found the institution which bears his name. Baron de Rothschild in his will appointed Dr. Trousseau to direct this foundation. Dr. Trousseau was the grandson of the famous clinician who died in 1867.

Diminution of Cases of Hydrophobia

Dr. Maurice Letulle, *agrégé* professor at the Paris medical college, during the last session of the Council of Hygiene and Salubrity, made a report on hydrophobia during the period from 1904 to 1909, setting forth the success obtained in the prophylaxis of rabies. While in Paris and the Department of the Seine, the number of biting animals remains about the same from one year to another, the proportion of animals in which hydrophobia has been recognized is continually and rapidly decreasing. While 474 animals were affected with hydrophobia in 1902, there were only 172 in 1904, 120 in 1905, 74 in 1906, 46 in 1907, 55 in 1908, and 13 in 1909. Of all animals the one most to be feared is the dog. In 1909, of 1,903 biting animals there were 833 dogs, 247 horses, 6 cats and 7 miscellaneous. Cases of hydrophobia are more frequent in the suburbs than in Paris, since in the six years studied, Paris has had only 211 cases, while the suburbs have had 249. It is at the Pasteur Institute, especially, that the progress of the prophylaxis of hydrophobia can be estimated. From 1904 to 1909 the number of persons bitten in the Department of the Seine amounted to 7,576, of whom 307 were bitten by animals known to be mad (183 in the suburbs and 124 in Paris). The number bitten by rabid animals was about 87 in 1904, and about 90 in 1905. It has progressively decreased to 65 in 1906, 35 in 1907, 24 in 1908, and 6 in 1909. Out of the 1,069 individuals cared for since 1904, fortunately there has been only one fatal case, which occurred in 1904. This was the last victim of the scourge in the region of Paris. Within six years only two cases of hydrophobia have been found in more than 68,000 stray dogs captured at the Fourrière (establishment where stray and abandoned dogs are received). Previously there was an average of 26 a year (155 from 1898 to 1903). Human hydrophobia, which caused twenty-two deaths as late as 1885, and twelve in 1901, has caused none for five years.

To what is this progressive disappearance of endemic rabies in Paris due? Dr. Letulle does not hesitate to attribute it to administrative measures. The capture of stray dogs in Paris has rendered valuable service because it has been carried on with great zeal and strictness. According as the pursuit is carried on methodically and without cessation, or relaxes for one reason or another, hydrophobia diminishes, seems to become extinguished, or revives and multiplies the number of its victims. It is necessary, then, to persist without slackening in the annual capture of twelve or fourteen thousand stray dogs in Paris if we wish to extirpate hydrophobia.

The Value of Tuberculin Therapy

The treatment of tuberculosis by tuberculin, which has been the subject of many recent investigations in Germany, has, up to the present, found few advocates among French physicians. The discussion held at the Congress of Internal Medicine proves that a change in this respect is now taking place. Dr. Louis Rénon, physician of the hospitals of Paris, declares that tuberculin, while constituting only a partial treatment of tuberculosis, still exercises an undeniable action in certain cases, notably in incipient tuberculosis and in torpid tuberculosis already treated or ameliorated by the usual medications and climate. Relative absence of fever is a necessary condition for the use of tuberculin in the patients not in hospitals. All tuberculins may be used on condition that one begins with relatively weak doses (1/500 mg.), increasing to 1/20 mg. It is necessary to avoid all apparent local or general reaction and to modify the injections according to the data furnished by the clinical examination. Dr. Bauer of Neufchâtel also recommends, in using tuberculin therapy, the greatest care in the observation of the individual reactions which cannot be foreseen. Dr. Mantoux of Cannes drew attention to the favorable results from tuberculin therapy in tuberculous lesions of the urinary organs; 48 per cent. of the patients improved and 33 per cent. were cured. Tuberculin therapy ought to be employed in cases in which the lesions are limited to the bladder in bilateral or unilateral renal tuberculosis at the beginning. Prof. J. Teissier of Lyons observed a very serious case of renal tuberculosis with numerous Koch bacilli in the urine in which tuberculin therapy led not only to disappearance of all the clinical phenomena and the improvement of the general condition, but also to the complete disappearance of the tubercle bacilli in the urine.

A New Diagnostic Sign in Pleuropulmonary Affections

On October 18, Dr. Hirtz, physician at the Necker Hospital, reported at the Académie de Médecine a diagnostic sign of some affections of the pleura or the lungs obtained by the percussion of the thorax under sustained inspiration. When the patient breathes normally percussion shows a dulness at the base of one or both lungs. One thinks of double or single pleurisy, but after making the patient take a forced and sustained inspiration, one percusses the thorax again, and finds that the point which seemed dull has become sonorous. It is not then an effusion; it is the pulmonary element which is incriminated. This sign permits the differentiation, without exploratory puncture, of congestion and pulmonary edema or spleno-pneumonia with pleural effusion. It makes it possible to say, then, in the course of pleurisy, if liquid is present or not. In short, certain apparently tuberculous congestions of the apex of the lung, in subjects of Bright's disease or heart disease, may receive their true interpretation through this new sign. In such case everything conspires to lead the clinician into error: the general condition of the patient, some anterior hemoptyses, and dyspnea; and in ordinary respiration, the dulness of the apices of the lungs appears incontestable and inclines the diagnosis toward tuberculosis; but as soon as percussion, under forced and sustained inspiration, is used, the tone becomes resonant and the error is avoided.

The Number of Fetal Heart-Beats and the Sex of the Child

At the Congrès de gynécologie, d' obstétrique et de pédiatrie, held at Toulouse, Dr. Fieux, *agrégé* at the Bordeaux medical college, communicated the results of investigations which he has made on fifty women, to find out what relation the number of the fetal heart-beats bears to the sex of the child. He presents his results in two tables. In the first, the fetal heart-beats never exceed 136; in the second they never fall below this figure. The first table gives seventeen boys (or 60 per cent.) and eleven girls (or 40 per cent.) The second table gives fifteen girls (or 68 per cent.) and seven boys (or 32 per cent.). Among the subjects with very high rhythms (160-180) girls are found almost exclusively. It is necessary to make the mother rest for some minutes before practicing auscultation and to auscultate the fetus during a period of calm. If these rules are observed the variations between the results of the various auscultations of one fetus are very slight, and the figure remains almost the same from the moment when the heart-beats are clearly perceptible to the end of the pregnancy.

Dangers of Poppy Decoctions

The employment of decoctions of the poppy-head as a soporific is very general in certain parts of France, especially in the north. Recently, near Lille, the physician who had made out the death certificate of an infant of 4 months refused to permit the burial without an inquest because he attributed the death to poisoning by poppy heads. The grandmother confessed that within 8 days the child had absorbed an infusion of three poppy heads in 1 liter (about a quart) of water. The autopsy showed no disease which might account for the death, but did disclose some signs of habitual opium intoxication, and on chemical analysis the viscera were found to contain a toxic quantity of morphin In reporting the case at the last session of the Société de médecine légale, Dr Dutilleul and M Bonn a chemist remarked that it was strange that while morphin and the other alkaloids of opium are among the poisonous substances which the pharmacist can deliver only on receipt of a medical prescription the substance from which these alkaloids are obtained is freely sold, not only by pharmacists, but by grocers, seedsmen and herb dealers A check on the sale of poppy heads would prevent the death of many children each year

BERLIN LETTER

(*From Our Regular Correspondent*)

BERLIN, Oct 28, 1910

Personal

Professor Brandenburg, director of the internal department of the district hospital of Grosslichterfeld, has been appointed head physician of the second internal department of the Rudolf Virchow hospital He is the successor of Professor L Kuttner, who, as previously announced, has been appointed director of the department

Professor Kossel director of the physiologic institute at Heidelberg has been awarded the Nobel prize in medicine for this year Kossel a pupil of Dubois Reymond, has especially distinguished himself by his valuable investigations of the nuclein metabolism in the cells

Professor Zangemeister a pupil of Professor Winter of Konigsberg, has been called to Marburg as director of the gynecologic clinic to succeed Professor Stockel ——Professor v Leube of Wurzburg celebrated the completion of his twenty fifth year as regular professor, October 31

Semicentennial of the Berlin Medical Society

Oct 26 the Berliner medizinische Gesellschaft celebrated its semicentennial The memorial meeting was of peculiar importance, as this society is not only the largest medical association in Berlin but also one of the most noted and largest in Germany and can look back on a notable past The society was formed by the union of two Berlin societies The older of these was founded in 1844 as a society for scientific medicine, and the younger was the Verein Berliner Aerzte, founded in 1858 In order to obviate any difficulties arising from the union of the two societies which took place in 1860, Rudolf Virchow resigned his position as president of the society for scientific medicine in favor of Albrecht v Grafe the president of the other society The Berlin Medical Society, in spite of the separation from it of numerous special associations of which that founded by v Leyden as the Verein fur innere Medizin was the first has still remained the central point of scientific medical activity in Berlin, and almost every Berlin physician considers it his duty to belong to it, so that at present it has more than 1,600 members As a result of the participation of the university teachers the scientific proceedings are always valuable and a number of important discoveries have been presented here for the first time As successors of v Grafe, Bernhardt von Langenbeck, Rudolf Virchow Ernst v Bergmann and finally H Senator have held the office of president Robert Koch Helmholtz and Pasteur were made honorary members a distinction which has seldom been bestowed On the occasion of the semicentennial the number of honorary members was considerably increased, including in addition to two living members of the society, two physicians practicing in Berlin Professor Waldeyer and the surgeon general of the Prussian army, v Schjerning, Naunyn (Baden Baden), Exner and Fuchs (Vienna), Golgi, Armauer Hansen (Christiania), Abraham Jacobi (New York), Fr Koranyi (Budapest), Keen (Philadelphia), Kitasato (Tokio), Laveran (Paris), Lépine (Lyons), Lister, Murri (Bologna), Pawlow (St Petersburg) Ramon y Cajal (Madrid), Retzius (Stockholm), Salomonsen (Copenhagen) and Rontgen (Munich) Senator was elected honorary president On the festival day it was announced that so far $15,000 (63,000 marks) had been subscribed by the members for the building of the projected Virchow House which is to be the special home of the society The widow of Virchow on the same occasion announced that she would make over to the new building the private collections and valuable memorials of Virchow.

Statistics of Hydrophobia for Prussia for 1909

In 1909 there were 406 injuries of human beings in Prussia by rabid animals or those suspected to be rabid The greatest number occurred as formerly in the eastern provinces, in those districts which touch the Russian boundary to the greatest extent The wounds were inflicted mostly by dogs, but to far less extent by cats, horses, cattle and deer Nineteen persons received wounds while tending two hydrophobic patients, 252 of the wounds were inflicted by animals which were certainly rabid, 374 of the wounded received the Pasteur inoculation in Berlin and Breslau Of the 374 inoculated, eight died (2 13 per cent) Of the thirty two who were not inoculated, two died (6 25 per cent), the latter were included among the twenty two persons who were bitten by animals certainly rabid, which gives a mortality of 9 1 per cent.

Communication of Typhoid by Butter and Cheese

Professor Gaffky, director of the institute for infectious diseases, in a report to the minister of education, states that there are no published accounts of the transmission of typhoid by butter and cheese Theoretically it may be said that according to previously published investigations, typhoid bacilli may remain viable in artificially infected butter from 21 to 27 days and that they pass for the most part into the cream that is used for butter when separated by the centrifuge In the curd obtained from milk (cheese made from sweet milk), the bacilli added to the milk are found, but they are rapidly killed by the acids that form in the curd, so that they cannot be demonstrated after the third day Gaffky therefore comes to the conclusion that butter made from sour cream, the curds from sour milk, and matured cheese are not likely to communicate typhoid To avoid communication by butter from sweet cream and cheese made from the same material, pasteurization of the milk is to be recommended, since a temperature of 60 C is sufficient to kill the typhoid bacilli in milk and does not affect the preparation or the taste of the products made from it

Carbohydrates in the Diet of Children

At the last session of the German pediatric society, Professor Langstein, head physician of the Augusta Victoria institute for prevention of infant mortality, made an interesting address on the rôle of carbohydrates in infant feeding The nutrition of the healthy child is to be sharply distinguished from that of the sick child For the improvement of artificial nutrition, it is necessary to determine the healthy infant's absolute requirement of carbohydrates For the artificial nutrition of the healthy child, no other viewpoint is appropriate except to furnish in a volume which as nearly as possible corresponds to the natural, as much nourishment as the law of energy requires for infants The natural flour suffices for the nutrition of healthy infants and it is not necessary to employ flour prepared for infants Overfeeding with sugar even if there are no alarming symptoms referable to the gastro intestinal tract, appears to be capable of leading to severe injury of the child's organism Exclusive nourishment with flour if long continued may lead to severe disturbances of nutrition Disproportionate nourishment with flour appears to lead to a chemical degeneration of the organism that involves a loss of immunity In the proper amount the carbohydrates are indispensable for the treatment of disturbances of nutrition in infants The enrichment of the diet by carbohydrates is of the greatest importance in the so called milk diet diseases (*Milchnahrschaden*) The importance of carbohydrates in these cases is due to the fact that they hinder the formation of soaps in the intestine. The various carbohydrates behave quite differently in reference to this power Milk sugar is the carbohydrate which is least adapted to the child whose nutrition is disturbed Cane sugar appears more efficient in these cases The best combination seems to be that of flour and malted preparations A complete loss of tolerance for carbohydrates is incompatible with the continuance of life

Statistics of Physicians in the German Empire

In the period from 1885 1907, while the population of the German Empire increased 32 per cent (from 46,700,000 to 61,700,000) the number of physicians increased 102 per cent (from 15,764 to 31,864) The percentage increase of physicians is thus more than three times as great as that of the population In 1885 the ratio was 3 4 physicians to 10 000 inhabitants, in 1907 it was 5 2 Professional incomes, diminished for this reason have been still more reduced by the social legislation which has included a large part of the private patients among the insured

Sleeping-Sickness

A discussion of the etiology and treatment of sleeping-sickness was held in the third Deutsche Kolonialkongress and the fourth International Congress for the Care of the Insane which are now in session in Berlin. At the first-named meeting, in the division on tropical medicine and tropical hygiene, the surgeon-general of the defense corps of the imperial colonial office, Professor Steudel, made a thorough report on the spread of sleeping-sickness. An increased spread of this disease, which had been known for more than a hundred years, was first noticed in the last decade of the last century in Angola on the Congo and finally on Victoria Lake. On Victoria Lake in German East Africa there are two foci, one in the district Bukoba with about a thousand patients. A wider spread is not to be feared as the tsetse fly is lacking in this district. The second focus is in the district of Schirati, close to the English border which has 800 or 1,000 patients. A limit to the further spread of the disease has also been surely established here through the extensive labors of sanitarians. At the third and largest [illegible] focus in German East Africa to the north o[illegible] the number of patients amounts to several thousand. The extermination of disease in this focus will require a great deal of work. In Kamerun single cases of sleeping-sickness have been repeatedly observed in the government hospital from the neighborhood of Duala; but no distinct focus of the disease could be found. In Togo there is a very old focus of sleeping-sickness, chiefly on the boundary river Volta. It appears that the disease in this old focus follows in general a milder course and shows less tendency to an epidemic character than on the Congo and in German East Africa. So far about 230 patients have been found. Dr. Hoffmann of Berlin gave his views of the etiology of sleeping-sickness. While some other possibilities of transmission are not entirely excluded, transmission by the bite of the fly *Glossina palpalis* is the only mode of importance for the epidemic spread of the disease. It has been shown that human beings may harbor infectious trypanosomes in the blood for as long as a year without signs of illness. These people are dangerous carriers and probably play the predominant rôle in the spread of the disease, as new flies may constantly receive the germs of the disease from them and spread them. In severely infected districts, half or two-thirds of the population are infected in this way and become carriers. The knowledge of the cause of the disease has already led to a well-planned and successful attack on this pest and promises to be still further successful. Privy-Councillor Uhlenhuth of Berlin described the treatment of sleeping-sickness. Arsenical preparations are of greatest importance.

The first successful treatment was inaugurated by the introduction of atoxyl by Thomas of Liverpool in 1905. Atoxyl is to-day at the center of medical interest. According to Uhlenhuth, atoxyl acts on the cells of the body and the leukocytes which produce substances which destroy the trypanosomes and prevent their multiplication. The knowledge of the action of atoxyl, regarding which opinions are not yet entirely clear, will be of great service in the search for new remedies. As Dr. Meixner says, the campaign against sleeping-sickness will be carried out on the lines laid down by R. Koch being directed against trypanosomes circulating in the blood and the flies which convey the disease. For the first purpose the patients must be collected at central stations, of which there are at present ten in the German colonies. From the beginning, under the supervision of nine physicians and sixteen sanitary assistants, 6,167 patients with sleeping-sickness have been treated. Ambulant treatment, as well as hospital treatment, has been extensively carried out. A large part is played by sanitary measures, consisting in trimming out the brush and cutting down the reeds, by which means the sensitive flies are destroyed. In addition the capture of flies and the destruction of crocodiles which form the sources of food for the flies are recommended. The natives, moreover, are transported to places free from these flies. Control of traffic and similar measures which hinder the spread of the disease are useful. Complete success is to be expected only after some years, but the results, especially of sanitary measures, are so far very satisfactory.

At the congress for the care of the insane Ehrlich delivered an address on his studies in the treatment of sleeping-sickness which was received with great interest. The similarity between paralysis and sleeping-sickness depends on the fact that the exciting causes of the two are similar in many respects and are influenced by the same remedy, and this influence is only a very partial one. Koch first succeeded by use of atoxyl, but the blindness arising from atoxyl in certain cases must be taken into account. A greater disadvantage of the atoxyl treatment is the fact that in only 10 per cent. of cases does a permanent cure result. Ehrlich tried to better these results by forming arsenic preparations which would act on the chemoceptor of the parasites without affecting the cells. This was effected by arsenophenylglycin, but great difficulties are experienced in the treatment of sleeping-sickness in this way because the response of parasites in various localities to treatment is not entirely uniform. While those in Togo are easily influenced by arsenicals, those at Kamerun and on the Congo are affected with difficulty; and while the patients on the Togo and the Congo are slightly susceptible to arsenic, those in East Africa are very susceptible, and, besides, the negroes resort to treatment too late. The changes in the spinal fluid are important for prognosis; and of greater importance is the fact that the races of trypanosomes which appear in relapses are biologically of different kind from the original and form different antibodies which do not prevent new infection and the number of th[illegible] large. A discontinuous treatment [illegible] has not been successful because a [illegible] parasite set in and symptoms of arsenic poisoning appeared, symptoms which are less prominent with "606." With the treatment styled by Ehrlich *therapia magna sterilisans*, by which the germ of the disease is supposed to be killed at one stroke, there are only three possibilities: (1) a fraction of the dose which can be tolerated is used and healing secured; or (2) very large doses, which may be dangerous, must be used, or (3) even these dangerous doses fail. In Togo a *sterilisatio magna* could be secured with doses which in East Africa did not result in a cure, and still endangered life, while in Leopoldville on the Congo, this amount would not produce a cure and yet was not dangerous to life.

As Ehrlich had taken these possibilities into consideration he brought his reserves into the fight against the trypanosomes by combining trypanred with the arsenic treatment. By this combined attack which had already been successful in animal experimentation, a cure was obtained which has already in some cases lasted for eight months. The similarity of paralysis and of sleeping-sickness is also shown in the fact that both are very difficult to influence if the germs have already invaded the spinal fluid, because the endothelium of the spinal meninges hinders the passage into this fluid of remedies with high molecular weight. The discovery of new remedies with greater penetrating power will assist in the solution of the problem of curing sleeping-sickness and paralysis. Ehrlich hopes to attain this solution with the assistance of psychiatrists. Professor Mott of London, director of the institute for sleeping-sickness in the English colonies, exhibited numerous instructive microscopic preparations which very distinctly showed the changes in the brain and in the lymph-vessels. Mott regards sleeping-sickness merely as a clinical phase of a general trypanosome infection, which manifests itself in the brain as a perivascular infiltration in the course of the brain vessels. For that reason he would like to see the name "sleeping-sickness" changed to "human trypanosomiasis." He also calls attention to the fact that in all human beings the same trypanosomes are present and the same insect is a conveyor of the disease. In the discussion Régis of Bordeaux emphasized the fact that the clinical difference between paralysis and sleeping-sickness is only slight. Professor A. Marie of Paris showed with the lantern a series of sleeping-sickness patients in the various stages of the disease and exhibited with the cinematograph living and moving trypanosomes and the spirochetes of chicken spirillosis, of syphilis and of relapsing fever.

BUDAPEST LETTER

Budapest, Oct. 22, 1910.

The Re-Inoculation of Persons Repeatedly Bitten by a Rabid Animal

Sometimes a person previously bitten and inoculated against rabies is again bitten by a mad dog. The question naturally arises whether inoculation should be done *de novo*, or whether it is superfluous? The same question presents itself also in regard to small-pox.

Before giving an answer to this very important question we must decide, said Professor Tangl in an address delivered before the Budapest Medical Society, whether the artificially produced immunity lasts for life or lapses after a certain time. In the latter case, obviously, a fresh inoculation is required. Jenner himself held the opinion that immunity once produced against small-pox infection lasted for life. Therefore he advised inoculation being performed in the first year of life. But experience has taught that the immunity disappears after a certain time; and a formerly protected person in a fresh small-pox epidemic easily contracts the disease anew, though in a milder form. For decades science was unable to clear up this question, because observations were taken only from statistics. Nowadays, experimental observations enable similar questions to be settled more quickly. We know, for example, that the immunity afforded by variola lasts about ten years. According to Haffkine, the immunity against plague commences within eight days of inoculation and lasts about as many months. It is important to know also the relations of the immunity produced against rabies.

The only information on this subject comes to us from Paris and from the Budapest Pasteur Institute. Pasteur kept his immune dogs under observation for many years. From time to time he tested their immunity against a lethal dose of the rabies virus. The immune dogs, when injected intraocularly with rabies virus, did not develop the disease, but the control dogs similarly infected with the same virus became mad. Pasteur mentions in one of his publications that in a certain dog immunity lasted at least 5 years.

A Prayer for Doctors and Nurses

BY WALTER RAUSCHENBUSCH

We praise thee, O God, for our friends, the doctors and nurses, who seek the healing of our bodies. We bless thee for their gentleness and patience, for their knowledge and skill. We remember the hours of our suffering when they brought relief, and the days of our fear and anguish at the bedside of our dear ones, when they came as ministers of thee. May we reward their fidelity and devotion by our loving gratitude, and do thou uphold them by the satisfaction of work well done.

¶ *We rejoice in the tireless daring with which some are now tracking the great slayers of mankind by the white light of science. Grant that under their teaching we may grapple with the sins which have ever dealt death to the race, and that we may so order the life of our communities that none may be doomed to an untimely death for lack of the simple gifts which thou hast given in abundance. Make thou our doctors the prophets and soldiers of thy kingdom, which is the reign of cleanliness and self-restraint and the dominion of health and joyous life.*

¶ *In their whole profession, strengthen the consciousness that their calling is holy and that they too are disciples of the saving Christ. May they never through the pressure of need or ambition surrender the sense of a divine mission and become hirelings who serve only for money. Make them doubly faithful in the service of the poor who need their help most sorely and may the children of the workingman be as precious to them as the children of the rich. Though they deal with the frail body of man, may they have an abiding sense of the eternal value of the life residing in it, that by the call of faith and hope they may summon to their aid the powers of thy all-pervading life.*

—*American Magazine, November, 1910.*

In 1892 Dr. Högyes, late professor of general pathology in the University of Budapest, published an article dealing with the question of the duration of immunity. He described his observations on eight immune dogs, on which Dr. Tangl repeated the test injections with rabies virus, after days, months, and after several years. The average result was that after the antirabic inoculation the immunity developed in a very short time (in one case after seven days) and lasted from four to seven years. A dog which was inoculated on Jan. 20, 1898, resisted the test-infection perfectly in February, 1901, so that it was absolutely immune after three years, even against the strongest virus. On July 31, 1907, i. e., after nine and a half years, it was again inoculated with rabies virus, but this time it became infected, and died on Aug. 27, 1907, with symptoms of paralytic rabies. A hare inoculated on the same day with the virus taken from the brain of the dead dog died after three days' illness on Sept. 27, 1907. The immunity, therefore, still existed after three years, but came to an end some time between three and nine and a half years. Another dog had the antirabic inoculations on Jan. 27, 1898. In 1901 Dr. Tangl found the dog absolutely immune. On Oct. 25, 1903, it died, with mild symptoms of rabies, confirmed by inoculation of a hare with the virus taken from the dog's brain. This dog, then, which after thirty-two months proved to be immune had lost its immunity after 5 years and 4 months.

So far these are the only experimental data bearing on the duration of immunity in the literature of the subject. From the results of these two experiments it appears that the average duration of immunity is between three and five years. Naturally individual factors play a certain rôle in this connection, because after two or three years all the eight dogs examined proved to be immune; we are therefore at liberty to suppose that the average limit of immunity may even exceed four years.

Up to the present time we have no data to indicate how far these facts hold good for human beings.

On account of the close relationship which exists between human and animal (particularly dog) rabies, both in the occurrence of the symptoms and in its course, we are justified in supposing that the process of immunity is analogous in men and dogs, and that, as Professor Högyes stated fifteen years ago, in all probability the immunity against rabies in man also expires after a certain time. Tangl concludes, therefore, that in the event of fresh bites by a mad dog revaccination is advisable in every instance, and is superfluous only when the fresh bite occurs at a very short interval after the previous antirabic inoculation.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Oct. 26, 1910.

Abundance of Congresses on Food and Nourishment

Vienna, or rather Austria, has witnessed this year quite an unusual series of scientific congresses, which had some bearing on medicine. Apart from the physiologists [The Journal, October 29, p. 1570] there was a congress of the balneologists. of those engaged in the refrigerating industry, and of those engaged in hunting and cattle feeding. Some points of interest to members of our profession were brought out. Thus, in the hunting congress, held in the Grand Hunting and Sports Exhibition in Vienna, a few weeks ago, the question of the failing meat-supply for our cities, with its consequences of rise in price of that article, was referred to in several papers. The possibility of furnishing ample meat-supplies from the forests of our country was shown, as there are sufficient stocks of hares, pheasants, partridges, roe and other venison, if only the population could be induced to form the habit of using them. Rabbits are hardly known here as food, while in France they are eaten in enormous quantities. The rapid industrialization of this country requires the supply of cheap nitrogenous and albumin-containing food. Fish were also shown to be a very good and cheap food for our country, if only popular prejudices were dispersed. From a medical point of view, this lecture was most useful, and in combination with another lecture, that on modern methods of freezing meat, it will form a starting-point for the modern provisioning of Vienna.

The scarcity of meat, or rather its high price, has called forth here the cry for frozen meat from Argentina. The quality of such food has been questioned, but the congress had opportunity to show that sound meat could be made to keep for months in a frozen state without the least injurious effect on the consumer. In the same manner, eggs, milk, fish and butter could be brought over and thus increase the regular intake by the individual of the requirements of a hard-working life.

This will, of course, be very important for the practitioner; for since tuberculosis is so frequent in the poorer classes of this city, cheap food will mean better chances of recuperation of many of his patients.

Marriages

James M. Marsh, M.D., to Miss May Bell Knight, both of Elkhorn, Wis., October 6.

Dwight Mackey, M.D., to Miss Ruth Bullock, both of Hobart, Ind., November 2.

Gael M. Adair, M.D., Anita, Iowa, to Miss Lela J. Hutton of Atlantic, Iowa, November 2.

Peter George Woods, M.D., Versailles, Mo., to Mrs. Osborn of High Point, Mo., October 26.

Elmer Hill, M.D., Huntsville, Wash., to Miss Bertha Dinsmore of Troy, Kan., October 26.

Frank S. Marnell, M.D., to Miss Fay Forbes, both of Nebraska City, Neb., November 4.

Charles Scudder Pool, M.D., to Miss Adelaide Chauncey, both of Brooklyn, N. Y., November 3.

Paul Frederick Straub, M.D., U. S. Army, to Miss Susan Olinger, at Dubuque, Iowa, November 3.

Walter E. Wright, M.D., Tulsa, Okla., to Miss Katherine Griggsby of Bardstown, Ky., November 1.

Jerome T. Quirk, M.D., New York City, to Miss Anne Darlington, at New York City, October 22.

Francis Marion Shook, M.D., U. S. Navy, to Mrs. Cornelia Gordon Upham; at New York City, November 3.

Oscar Hunter McClung, M.D., Fairfield, Va., to Miss Eugenia Harman of Richmond, Va., November 2.

Paul P. Allen, M.D., Chambersburg, Pa., to Miss Gertrude Wheeler of Germantown, Philadelphia, October 27.

Carl D. Chapell, M.D., Flint, Mich., to Miss Elizabeth M. Carroll of New Orleans, at Flint, November 2.

Thomas Joseph Norton, M.D., Pittsfield, Mass., to Miss Teresa Manning of Worcester, Mass., November 15.

George Torance Crosbie, M.D., Belle Vernon, Pa., to Miss Anna Mae Myers of North Charleroi, Pa., October 26.

George Canning Wankel, M.D., Deerfield, N. Y., to Miss Adelaide Pelletier of Bloomingdale, N. Y., October 27.

Peter Aloysius Slattery, M.D., White Earth, Minn., to Miss Nelley Evelyn Utman of Minneapolis, October 9.

Edward Melverton Trainor, M.D., Stanley, N. Dak., to Miss Lillian Victour Landquist of Minneapolis, October 25.

George W. Pugsley, M.D., Panama, Iowa, to Miss Grace Thomas of Plattsmouth, Neb., at Daykin, Neb., October 26.

William H. McBean, M.D., Los Angeles, to Anna M. Gutzwiller, M.D., of Eldridge, Cal., at Los Angeles, October 19.

James Bourke, M.D., U. S. Army, to Miss Josephine Margaret Ott of Leavenworth, Kan., at Jefferson City, Mo., November 3.

Charles Milton Murrell, M.D., Elida, N. Mex., to Miss Clara Loraine Rademacher of Clinton, Iowa, at Savanna, Ill., October 26.

Deaths

John Marshall Allen, M.D. St. Louis Medical College, 1854; a member, and in 1899 third vice-president of the American Medical Association; died at his home in Liberty, Mo., November 1, from pneumonia, aged 77. Dr. Allen represented Clay County in the legislature in 1884 and 1885; served throughout the Civil War in the State Guard of Missouri and the Confederate service as brigade surgeon and finally as chief surgeon of the district of Mississippi and Louisiana. He was one of the organizers and professor of diseases of the abdomen in the University Medical College of Kansas City, and later president of the college.

Adrian Snydam Polhemus, M.D. Bellevue Hospital Medical College, 1882; major and surgeon, U. S. Army, retired; died in Portland, Ore., October 28, from nephritis, aged 53. He was appointed an assistant surgeon in the Army in December, 1883, and was promoted to captain in 1888. During the war with Spain he served as brigade surgeon of volunteers; was promoted to major and surgeon in the regular establishment in 1901, and was retired on account of disability in line of duty, December 5, 1904.

Edgar Henry Douglas, M.D. Dartmouth Medical School, Hanover, N. H., 1890; of Little Falls, N. Y.; a member of the American Medical Association and of the New York and New England Association of Railway Surgeons; formerly mayor and health officer of Little Falls; local surgeon of the New York Central Railroad, and a member of the Board of U. S. Pension Examiners, and of the staff of the Little Falls Hospital; died in the Utica Hospital, October 29, from cholelithiasis, aged 43.

Michael Brown Van Buskirk, M.D. University of Pennsylvania, Philadelphia, 1866; of Aurora, N. Y.; a member of the Medical Society of the State of New York; formerly health officer of Ledyard, N. Y.; a veteran of the Civil War; a member of the New York legislature in 1884 and 1885; died at the home of his daughter in New York City, October 31, from arteriosclerosis, aged 70.

Anselm D. Price, M.D. University of Louisville, 1865; a member of the American Medical Association, and a member of the House of Delegates from Kentucky; formerly president of the Kentucky State Medical Society; medical referee for Mercer County and a member of the county board of health for several years; died at his home in Harrodsburg, November 11, from nephritis, aged 70.

Addison Julius Tanner, M.D. New York University, New York City, 1894; of Meriden; a member of the Connecticut State Medical Society; vice-president of the Meriden City Medical Association; for several years town physician; while crossing an electric railway track in Berlin, Conn., in his automobile, October 29, was struck by a car and instantly killed, aged 40.

Edward Holman Hamill, M.D. New York University, New York City; 1869; consulting medical director of the Prudential Insurance Company, Newark, N. J.; a Confederate veteran; at one time president of the Association of Life Insurance Medical Directors of America; died at his home in Chatham, N. J., October 30, aged 66.

Walter E. Delabarre, M.D. New York Homeopathic Medical College, New York City, 1891; formerly of New York City; assistant surgeon of the New York Ophthalmic Hospital; medical director of Rosemont Springs Sanitarium, White Plains, N. Y.; died at his home in White Plains, October 30, from interstitial nephritis, aged 52.

John Edwin Allen, M.D. Bellevue Medical College, 1875; for twenty-five years connected with the department of health of New York City; at one time professor of anatomy in his alma mater; for twenty years surgeon of the Seventy-First Infantry, N. G., N. Y., died at his home in New York City, October 25, from nephritis, aged 63.

James D. MacGaughey, M.D. Jefferson Medical College, 1870; a member of the American Medical Association; a member of the Connecticut State Legislature in 1880, and for nine years medical examiner and registrar of vital statistics of Wallingford; died at his home, October 31, from bronchopneumonia, aged 62.

William Richard Hobbs, M.D. Detroit College of Medicine, 1893; a member of the Nebraska State Medical Association; of Omaha; an eye, ear, nose and throat specialist of Omaha; and surgeon to the Douglas County and Swedish Mission Hospitals; died at his old home in Guelph, Ont., October 17, aged 49.

Louis Marshall, M.D. Medical College of Ohio, Cincinnati, 1904; a member of the Kentucky State Medical Association; of Washington, Ky.; health officer and a member of the board of health of Mason County, Ky.; died in Fort Worth, Texas, November 2, from hemorrhage of the lungs, aged 37.

Thomas V. B. Embree, M.D. Willamette University, Salem, Ore., 1882; a pioneer physician of Polk County, Ore., and commander of the Oregon Indian War Veterans on account of service in the Yakima Indian War of 1855 and 1856; died at his home in Dallas, October 26, from nephritis, aged 74.

William F. Scott, M.D. Transylvania University, Lexington, 1850; of Somerset; surgeon in the Federal service during the Civil War, and at one time superintendent of the Eastern Kentucky Hospital for the Insane, Lexington; died in the Somerset Sanitarium, October 26, from senile debility, aged 91.

Harris Burton Lochhead, M.D. Jefferson Medical College, Philadelphia, 1902; a member of the Medical Society of the State of Pennsylvania; of Pittston, Pa.; a member of the staff of the Pittston Hospital; died in the White Plains, N. Y., Hospital, October 25, aged 35.

John Campbell Flynn, M.D. Pulte Medical College, Cincinnati, 1879; Cincinnati College of Medicine and Surgery, 1886; health officer of Warren village and township, Macomb County, Mich.; died at his home in Warren, October 15, from chronic gastritis, aged 60.

Nelson G. Coffin, M.D. Medical College of Ohio, Cincinnati, 1847; Illinois Army Board, 1862; assistant surgeon of the One Hundredth and Seventh Illinois Volunteer Infantry during the Civil War; died at his home in Monticello, Ill., November 1, aged 90.

William Wilberforce Baldwin, M.D. Long Island College Hospital, Brooklyn, N. Y., 1876; for more than twenty-five years a practitioner of Rome and Florence, Italy; died at the family home in Great Bend, Pa., October 17, from cerebral hemorrhage, aged 60.

George Austin Bowen, M.D. New York University, New York City, 1863; for several terms a member of the Connecticut legislature; surgeon-general of the state in 1895 and 1896; died at his home in Woodstock, October 30, from nephritis, aged 69.

Garrett Beverly Blackwell, M.D. Eclectic Medical Institute, Cincinnati, 1885; of Scotts Mills, Ore.; while apparently asleep on a railway track between Woodburn and Hubbard, Ore., September 6, was struck by a train and instantly killed, aged 55.

John B. Stevens (license, New Hampshire, 1897); for many years a practitioner of Lowell, Mass., and surgeon of the Thirteenth New Hampshire Volunteer Infantry during the Civil War; died at his home in Merrill, N. H., May 8, 1909, aged 77.

John M. B. Rogers, M.D. College of Physicians and Surgeons, Baltimore, 1877; of Ellicott City; a member of the Medical and Chirurgical Faculty of Maryland; died at the home of his sister in Govans, Md., October 31, from typhoid fever, aged 62.

Samuel H. Friend, M.D. University of Pennsylvania, Philadelphia, 1888; formerly a member of the American Medical Association; a member of the State Medical Society of Wisconsin; died at his home in Milwaukee, October 30, aged 48.

Rufus O. Snider, M.D. Trinity Medical College, Toronto, Ont., 1896; of Toronto; who was injured in a collision between his automobile and a street car a year ago, was found dead in bed, September 16, from cerebral hemorrhage, aged 45.

Joseph Lacy Brayshaw, M.D. College of Physicians and Surgeons, Baltimore, 1888; of Friendship, Md., a member of the Medical and Chirurgical Faculty of Maryland; died in Sibley Hospital, Washington, D. C., October 30, aged 55.

William Henry Meyers, M.D. Philadelphia University of Medicine and Surgery, 1861; for many years surgeon of the Baltimore and Ohio Railroad, at Myersdale, Pa.; died at his home in that place, October 30, from diabetes, aged 70.

William James Telfer, M.D. McGill University, Montreal, 1890; a member of the Montreal Medico-Chirurgical Society; and demonstrator of chemistry in his alma mater; died recently in Burgoyne, Que., aged 46.

Alexander C. Harlan, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1886; formerly of McCook, Neb.; a veteran of the Civil War; died at the home of his niece near Hillsboro, Iowa, October 23, aged 67.

William Perry Baird, M.D. University of Michigan, Ann Arbor, 1858; acting assistant surgeon in the Navy during the Civil War; died at his home in Northboro, Mass., September 10, from angina pectoris, aged 80.

Joseph Frank Geenan, M.D. Rush Medical College, 1893; formerly of Toluca, Ill.; for four years coroner of Marshall County; died at his home in Beloit, Kan., October 20, from disease of the kidney, aged 42.

Samuel W. Edmonds, M.D. University of Michigan, Ann Arbor, 1868; of Alexander, Ill.; a veteran of the Civil War; died in Passavant Hospital, Jacksonville, November 2, from typhoid fever, aged 70.

Robert Dunlop, M.D. Hospital College of Medicine, Louisville, 1884; for many years physician to the Little Sisters of the Poor; died at his home in Louisville, November 9, from uremia, aged 57.

Gilbert Potter Bennett, M.D. Hahnemann Medical College, Chicago, 1881; formerly of Sedalia, Mo., and San Bernardino, Cal.; a veteran of the Civil War; died at his home, October 18, aged 80.

P. A. Gastonguay, M.D. Laval University, Quebec, 1904; of Quebec; while canoeing on the Jacques Cartier River, near St. Catherine, Que., October 9, was drowned by the upsetting of his canoe.

Norman McLeod Carter, M.D. College of Physicians and Surgeons, New York City, 1904; of Huntington, L. I.; died at Saranac Lake, N. Y., November 2, from tuberculosis, aged 34.

Oliver Cromwell Kirby, M.D. College of Physicians and Surgeons, Chicago, 1909; of Avondale, Chicago; died in the University Hospital, Chicago, October 29, from typhoid fever, aged 25.

Robert Swepson Sims, M.D. Missouri Medical College, St. Louis, 1883; formerly of Fruitland, Texas; died at his home in Fayetteville, Ark., January 1, from gastric ulcer, aged 69.

Ernest Stuart Albee, M.D. Rush Medical College, 1900; a member of the State Medical Society of Wisconsin; died at his home in Oshkosh, November 1, from nephritis, aged 34.

David Sanford Watson, M.D. Reform Medical College of Georgia, Macon, 1860; a Confederate veteran; died at his home near Anderson, S. C., April 19, 1909, aged 79.

Benjamin Russell Walker (license, Iowa, years of practice, 1886); of Decatur County, Iowa; died in the County House, Leon, Dec. 21, 1909, from arteriosclerosis, aged 80.

William Thomas Hutchins, M.D. Memphis (Tenn.) Hospital Medical College, 1889; died at his home in Gulfport, Miss., September 24, from cirrhosis of the liver, aged 51.

Royal E. Cochrane, M.D. University of Buffalo, N. Y., 1872; a veteran of the Civil War; died at his home in Penfield, N. Y., October 22, from angina pectoris, aged 66.

David N. Fansler, M.D. University of Wooster, Medical Department, Cleveland, 1874; died at his home in Marion, Ind., September 5, from senile debility, aged 80.

Lewis William Krieger, M.D. Jefferson Medical College, 1892; of Peoria, Ill.; died at St. Francis Hospital in that city, October 23, from cerebral hemorrhage, aged 51.

James Edgar Wall, M.D. University of Lousiville, 1880; for four years health officer of Panola County; died at his home in Carthage, Texas, October 22, aged 53.

John P. Cloyd, M.D. Rush Medical College, 1869; of Georgetown, Ill.; died at the home of his daughter in that place, October 29, from senile debility, aged 72.

Eady Stevenson, M.D. Cleveland University of Medicine and Surgery, 1859; M.R.C.P. and S., Ontario, 1879; of Vancouver, B. C.; died recently.

Frederick W. Neal, M.D. Rush Medical College, 1891; died at his home in Grand Rapids, Mich., May 27, from sarcoma of the hip, aged 43.

Charles Henry Shepard, M.D. New York Medical College, New York City, 1859; died at his home in Brooklyn, N. Y., October 29, aged 85.

Emma M. Linden, M.D. Willamette University, Salem, 1899; died at her home in Portland, Ore., October 25, aged 52.

Practical Demonstration of the Dangers of Optometry

To the Editor:—Knowing the active interest of the Association in the wide-spread agitation for laws licensing opticians to examine for refractile errors and prescribe glasses, I have thought that a striking instance of the dangers of this proceeding which has just come to my notice might well be recorded. A man of 34 consulted me this week because of a severe and increasing headache of three months' duration. Three weeks ago he went to one of the large opticians of New York because of some trouble with his eyesight, and had glasses prescribed for him by an optometrist. He did not have a refractile error of consequence, but a high grade of choked disc in both eyes and was suffering from brain tumor. Of course, a decompression operation three weeks ago would have preserved much more sight than can be expected now, and the blame for the loss of this valuable time is to be placed wholly on the legal recognition of optometrists, which was given in New York State last winter.

The optometry question is in my opinion but one phase of a larger problem which must eventually be settled rightly in this country, but which we can scarcely expect to have so settled until general education in the fundamental facts of physiology and pathology is much more wide-spread, and perhaps not until our therapeutic resources become more comparable with our diagnostic ones. No person, whether he styles himself optometrist, osteopath, mental healer, or any other sectarian name, should be recognized by law as competent to treat disease until he has been thoroughly trained in the science of diagnosis. This, for every specialty, no matter how small, demands, as a minimum training, the present course of instruction in the whole of medicine required of candidates for license as physicians. No part of the human body can be arbitrarily separated from its vital connection with the whole organism. The sooner the public recognizes this fact the better.

THEODORE C. JANEWAY, New York.

Hexamethylenamin in Pellagra

To the Editor:—In THE JOURNAL, November 5, p. 1663, Dr. Bagby discusses the hexamethylenamin treatment of pellagra I have used the same remedy in two cases, giving a dose of 5 grains three times a day. The progress of each patient, while not nearly so remarkable as in Dr. Bagby's case, was very satisfactory. A week ago, however, one of them, who had had an organic heart lesion for years, died suddenly while talking to some friends. This patient had so far recovered as to be able to work half a day at a time. The other patient is improving rapidly. The arsenic treatment has been kept up, and I have been doubtful whether the improvement was due to the hexamethylenamin, the arsenic, or the time of the year, or to these three combined. I began the hexamethylenamin at the suggestion of Dr. Manfred Call of Richmond, who has, I think, been using it for several months.

WALTER E. VEST, Meherrin, Va.

Chinosol—A Correction

To the Editor:—In an article by Dr. Wilbur E. Post and myself on "The Comparative Efficiency of Some Common Germicides" which appeared in THE JOURNAL, Nov. 5, 1910, the value of chinosol as a germicide was the subject of criticism. Since the publication of the article, my attention has been called to the fact that chinosol is no longer advertised as a germicide nor has it been since the Council on Pharmacy and Chemistry proved to the satisfaction of its manufacturer that, while it possessed antiseptic powers, its germicidal action was practically nil Our criticisms of this preparation, therefore, were without foundation Chinosol was examined by us because at the time our experiments were made this product was advertised and sold as a germicide. In publishing the results of our work reference to chinosol should, of course, have been omitted.

HOMER K. NICOLL, M.D., Chicago.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed Every letter must contain the writer's name and address, but these will be omitted, on request.

PLANS FOR HOSPITALS

To the Editor:—I desire information regarding the size, cost of building and arrangement of a hospital in a small city. Articles have been published in THE JOURNAL on this subject. Please give me the dates

WILLIAM F. ROSS, New Kensington, Pa.

ANSWER.—The following original articles and abstracts have appeared in THE JOURNAL:

SWELLING OF NOSE AND UPPER LIP

To the Editor:—I have a patient, a woman, aged about 35, in good health, who yet has marked swelling of nose and upper lip every morning This goes down slightly toward evening and appears again in the morning There is scarcely any redness of the skin I have examined all the organs and find no cause for the phenomenon I have tried various treatments with no effect. The only symptom is the swelling Probably you could suggest some line of treatment

INQUIRER.

ANSWER—It would be impossible to give intelligent advice without knowing more about the case Is the condition due to some error in diet, to derangement of digestion from other causes, to some medicine the patient may be taking, to some condition of sleeping apartment, to late supper, to anemia, to malaria, to angioneurotic edema, etc? It would not be safe in such a case to accept as final the statement that the patient is in good health.

The Public Service

Medical Department, U. S. Army

Changes during the week ended Nov 12, 1910

Mason, George E, D S, Nov 1, left Fort Snelling, Minn, en route to Fort Lincoln, N D, for temporary duty

Leslie, Samuel H, D S, Oct 27, reported for temporary duty at Fort Robinson, Neb

Stallman, George E, D S, Nov. 2, reported for temporary duty at Fort McIntosh, Texas

Ford Clyde S, major, Nov 1, reported for temporary duty at Fort Yellowstone, Wyo

Wilcox Charles, major, Nov 3, relieved from duty at Fort Totten, N Y., and ordered to Fort Sheridan, Ill, for duty.

Dougherty, James C, M R C, Nov 3, granted two months' leave of absence

Cutliffe, William O, M R C, Nov 3, ordered to Walter Reed General Hospital, Takoma Park, D C, for observation and treatment

Church, James R, major, Nov 5, relieved from duty at Fort Ontario, N Y, and ordered to Fort Williams, Me, for duty

Miller Edgar W, captain, Nov 5, relieved from duty at Fort Williams Me, and ordered to Fort Ontario, N Y, for duty

Bartlett, C J, captain, Nov 5, granted twenty one days' leave of absence

Shaw, Henry A major, Nov 7, granted leave of absence to include Dec 5 1910

Bernheim, J R, D S, Nov 8, granted two months' leave of absence on arrival at San Francisco

Perley Harry O, colonel, Nov 3, left Denver on thirty days' leave of absence

Crabtree George H captain, Nov 4, reports on forty two days' leave of absence from Culebra Canal Zone

Sherwood, J W, M R C, Nov 9, reported for temporary duty at Fort Andrews, Mass

Bannister, John M, colonel, Nov 9, on his own application is retired from active service on Dec 31, 1910, after more than thirty one years' service

Porter, Ralph S, captain, Nov 9, granted four months' leave of absence

Hereford, John R, M R C, Nov 10, granted leave of absence for one month and twenty days

McKinney, Garfield L, lieutenant Nov 9, on arrival at San Francisco will report to commanding officer, Army General Hospital, at that place, for duty

Medical Corps, U. S. Navy

Changes during the week ended Nov 12, 1910

Green, E H, medical director detached from command of the naval hospital, New York, and ordered to duty at the naval recruiting station New York

Gatewood, J D, medical inspector, ordered to duty as president of the naval examining and naval medical examining boards, at the naval medical school, Washington, D C

Byrnes, J C, medical inspector, detached from command of the naval hospital, Newport, R I, and ordered to command the naval hospital, New York

Diehl, O, medical inspector, ordered to command the naval hospital, Newport, R I

Farenholt, A, surgeon, detached from the *California* and ordered to command the naval hospital, Puget Sound Wash

Morris, L, surgeon, ordered to the naval medical supply depot, New York

Parker E G, surgeon, detached from the *South Dakota* and ordered home to await orders

Shipp, E M, surgeon detached from duty as president of the naval examining and naval medical examining boards at the naval medical school, Washington, D C, and ordered to continue other duties

Vickery, E A, passed asst surgeon, detached from the *Solace* and ordered to the *Maryland*

Dollard H L, passed asst surgeon detached from the naval hospital, Mare Island, Cal, and ordered to the navy recruiting station, Kansas City, Mo

May, H A, passed asst surgeon, detached from the bureau of medicine and surgery, Navy Department, and ordered to duty at the naval hospital, Las Animas, Colo

Eytinge, E O J, passed asst surgeon, detached from the naval hospital, Norfolk, Va, and ordered to the *South Dakota*

Baker, M W, passed asst surgeon, ordered to duty at the naval hospital, New York

Camerer, C B, asst surgeon detached from the naval hospital, Las Animas, Colo and ordered to the *California*

Thompson F W, asst surgeon, detached from the navy recruiting station, Kansas City, Mo, and ordered to the *Montgomery*

Bunker C W O, asst surgeon, detached from the *Montgomery* and ordered to duty at the naval hospital, Mare Island Cal

Garrison, H A, asst surgeon, ordered to duty at the naval hospital, Norfolk Va

Taylor J L, passed asst surgeon detached from the naval hospital, Las Animas Colo and ordered to duty at the naval hospital, Naval Home, Philadelphia

Guest, M S, surgeon, detached from command of the naval hospital, Pensacola, Fla, and ordered to continue other duties

Seaman, W, surgeon detached from the navy recruiting station, New York, and ordered to command the naval hospital, Pensacola, Fla

Dykes, J R, passed asst surgeon, ordered to duty at the Naval Medical School Hospital, Washington, D C

Woodward J S, passed asst surgeon, detached from the *Birmingham* and ordered home to await orders

Brooks, F H, passed asst surgeon, detached from the navy recruiting station, Omaha, and ordered to the *Birmingham*

Straeten, R J, passed asst surgeon, detached from the naval proving ground, Indian Head, Md, and ordered to the navy recruiting station, Omaha

Higgins, M E, asst. surgeon, ordered to the naval proving ground, Indian Head, Md

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended Nov 9, 1910

Mead, Frank W, surgeon on being relieved by Surgeon J. B Stoner, directed to proceed to Vineyard Haven, Mass, and assume command

Carrington, Paul M, surgeon, relieved from duty at San Diego Cal, and directed to proceed to Port Townsend, Wash, and assume command

McIntosh, W P, surgeon, bureau order dated Oct 27, 1910, detailing him as chairman of board to examine officer of Revenue Cutter Service, revoked.

Stoner, James B, surgeon, on being relieved by Surgeon P M. Carrington, directed to proceed to Savannah, Ga, and assume command

Guiteras, G M, surgeon, on being relieved by Passed Assistant Surgeon R H von Ezdorf, directed to proceed to Galveston, Texas, and assume charge

Oakley James H, surgeon on being relieved by Passed Assistant Surgeon B H Earle, directed to proceed to Philadelphia and report to Surgeon W G Stimpson for duty in the medical examination of arriving aliens

Wickes Henry W surgeon relieved from duty at New Orleans and directed to proceed to Cairo, Ill and assume command

Clark, Taliaferro, P A surgeon, relieved from duty at Philadelphia and directed to proceed to Evansville, Ind, and assume command

Von Ezdorf R H P A surgeon, relieved from duty at New Orleans Quarantine Station, and directed to proceed to Mobile and assume command

Moore, Dunlop P A surgeon detailed as chairman of board to examine officer of Revenue Cutter Service

Corput, G M P A surgeon relieved from duty at Galveston, Texas, and directed to proceed to New Orleans Quarantine Station and assume command

Goldberger, Joseph, P A surgeon, leave of absence for one month and 4 days from Sept 26, 1910, amended to read twenty six days from Sept 26 1910

Gwyn, M K P A surgeon detailed as recorder of board to examine officer of Revenue Cutter Service

Wilson Robert L, P A surgeon, on being relieved by Surgeon Henry W Wickes, directed to proceed to Charleston Quarantine Station and assume command

Earle, B H P A surgeon, on being relieved by Passed Assistant Surgeon R L Wilson directed to proceed to Port Townsend Quarantine Station and assume command

Lloyd B J, P A surgeon, relieved from duty at the Hygienic Laboratory, and directed to proceed to Seattle, Wash, and assume charge

McCoy, George W, P A surgeon, relieved from duty at San Francisco, and directed to proceed to Honolulu T H, and report to the Director of the Leprosy Investigation Station for duty

Chapin, C W, asst surgeon on being relieved by Passed Assistant Surgeon B J Lloyd, directed to proceed to San Francisco and report to Surgeon Rupert Blue for duty

Grimm, R M asst surgeon, on being relieved by Passed Assistant Surgeon Taliaferro Clark directed to proceed to Washington, D C and report to the Director of the Hygienic Laboratory for duty

Thompson, L R, assist surgeon, directed to proceed to Washington, D C, and report to the Director of the Hygienic Laboratory for temporary duty

Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course]

Fourth Month—Second Weekly Meeting

ACQUIRED DEFORMITIES OF THE SPINE

Scoliosis

Etiology· Congenital or acquired, habitual or fixed deformity. Age and sex Faulty attitudes, occupations, unequal vision or hearing, torticollis, empyema, rickets, heart disease, etc

Symptoms 1 Postural or functional scoliosis Deformity, convexity of spine, shoulders, hips Effect of bending forward, of suspension. Location of convexity Results 2 Structural or fixed scoliosis. One or more curves, usual locations, prominences, depressions, rotation Effect of bending forward and of suspension Shoulders and hips General symptoms, pain, dyspnea, impaired health.

Treatment 1 Postural cases: hygiene, gymnastics, etc 2 Structural cases (a) Correct deformity by active exercises, by apparatus, jackets, etc, (b) retention of improved position

NON-TUBERCULOUS AFFECTIONS OF THE SPINE

Acute Osteomyelitis Etiology Symptoms. Treatment.

Syphilis of the Spine Diagnosis Treatment

Infectious Arthritis of the Spine: Typhoid Spine: Pathology, diagnosis Gonorrheal Spine: Diagnosis, treatment.

Rigidity of the Spine 1 Spondylitis deformans: Pathology; diagnosis 2 Chronic ankylosing inflammation of the spine· Etiology, pathology, clinical types 3 Muscular spinal rigidity. 4 Traumatic spinal rigidity.

State Boards of Registration

COMING EXAMINATIONS

CALIFORNIA: Los Angeles, December 6-9. Sec., Dr. Charles L Tisdale, 929 Butler Bldg., San Francisco.

DELAWARE: Regular, Dover, December 13-15; Homeopathic, Wilmington, December 13-15. Secretary of the Medical Council, Dr. H. W. Briggs, Wilmington.

KENTUCKY: Louisville, December 15-17. Sec., Dr. J. N. McCormack, Bowling Green.

MARYLAND: 1211 Cathedral St., Baltimore, December 13-16. Sec, Dr. J. McPherson Scott, Hagerstown.

OHIO: Cincinnati, December 6-8. Sec., Dr. George H. Matson, State House, Columbus.

PENNSYLVANIA: Regular and Homeopathic, Philadelphia, December 6-9; Eclectic, Harrisburg, December 6-9. Secretary of the Medical Council, Dr. Nathan C Schaeffer, Harrisburg.

TEXAS: Palestine, November 22-24. Sec., Dr. R. H. McLeod.

VIRGINIA: Lynchburg, Dec. 20-23. Sec., Dr. R. S. Martin, Stuart.

Preliminary Educational Requirement in Texas

The following communication has been received from Dr. *M. E. Daniel, Honey Grove, Texas, chairman of the college* and reciprocity committee of the Texas State Board of Medical Examiners:

"This is to notify prospective medical students and all concerned, that before matriculation in the medical colleges of Texas is permissible, it is necessary to procure an entrance certificate from the State Board of Medical Examiners. This means that the authorities of the several medical colleges no longer pass on the literary credentials of applicants for matriculation. This function is now exercised by the State Board of Medical Examiners.

"To be eligible for examination or reciprocity, all Texas students matriculating in other states since 1908, must comply with this requirement. Non-residents desiring matriculation are required to comply with this regulation whether they expect to take the state medical board examination or not. Texas medical colleges are required to matriculate resident and non-resident students on equal terms.

"Residents and non-residents alike, who comply with the entrance requirements in such states as have reciprocal relations with Texas, will be accepted for matriculation, examination or reciprocity, provided literary credentials are acted on and credits determined by the State Medical Examining Board or other legally designated authority independent of medical college authorities or faculties.

"Residents and non-residents matriculating in states other than reciprocal states, and who expect future legalization in Texas, must comply with this regulation, but matriculants of such of these states as maintain and enforce an educational standard equal to our own, will be accepted. But those matriculating in states which maintain no fixed literary prerequisite, where the college faculties have the sole prerogative of passing on and determining the literary qualifications of medical students, will be barred unless they possess an entrance certificate issued by this board or from some other state having reciprocal relations with Texas. It is not sufficient to possess the necessary literary credential with the view of submitting it after graduation; the required entrance certificate must be procured before matriculation.

"Texas now reciprocates with the following states: Arkansas, Missouri, Illinois, Indiana, Iowa, Michigan, Kentucky, Maine, Nebraska, Minnesota, District of Columbia, West Virginia, Virginia, Maryland, Wisconsin, Vermont, North Dakota, Ohio, New Jersey, Kansas and Nevada.

"Full particulars can be had by addressing the secretary of the board, Dr. R. H. McLeod, Palestine, Texas."

Arizona October Report

Dr. Ancil Martin, secretary of the Board of Medical Examiners of Arizona, reports the written examination held at Phoenix, October 3-4, 1910. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 4, of whom 3 passed and 1 failed. The following colleges were represented:

PASSED College	Year Grad.	Per Cent.
Tulane University of Louisiana	(1893)	75.2
Baltimore Medical College	(1906)	79.2
University of Pennsylvania	(1891)	75
FAILED		
Medical College of South Carolina	(1910)	71.2

Indiana Reciprocity Report

Dr. W. T. Gott, secretary of the Indiana Board of Medical Registration and Examination, reports that thirty-one candidates have been licensed through reciprocity from January 1, to October 15, 1910. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
George Washington University	(1901)	Illinois
Rush Medical College	(1906) (1908)	Illinois
Illinois Medical College	(1905)	Illinois
Coll. of Physicians and Surgeons, Chicago	(1907) (1908)	Illinois
Jenner Medical College	(1904)	Illinois
Northwestern University Med. School	(1906) (2, 1908)	Illinois
American College of Medicine and Surgery	(1903)	Illinois
American Medical Missionary College	(1902)	Kansas
Medical College of Indiana	(1907)	Colorado
Fort Wayne College of Medicine	(1882) (1886)	Ohio
University of Iowa, College of Medicine	(1898)	Iowa
Louisville Medical College	(1907)	Kentucky
University of Louisville	*(1903) (1908)*	*Kentucky*
Louisville and Hospital Medical College	(2, 1908)	Kentucky
Hospital College of Medicine, Louisville	(1900)	Kentucky
College of Physicians and Surgeons, Baltimore	(1896)	Virginia
Detroit College of Medicine	(1897)	Michigan
University of Michigan, Dept. of Med. and Surg.	(1908)	Michigan
Eclectic Medical University, Kansas City	(1906)	Missouri
Beaumont Hospital Medical College	(1900)	Kansas
Western Reserve University	(1908)	Ohio
Eclectic Medical College, Cincinnati	(1901)	Ohio
Vanderbilt University	(1896)	Kentucky
University of Tennessee	(1899)	Kentucky

Utah October Report

Dr. G. F. Harding, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, October 3-4, 1910. The number of subjects examined in was 22; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 10, all of whom passed. Seven candidates were licensed through reciprocity. The following colleges were represented:

PASSED College	Year Grad.	Per Cent.
Northwestern University Medical School	(1910)	75.3
Rush Medical College	(1910)	80.4, 80.9
St. Louis University	(1910)	82
St. Louis College of Physicians and Surgeons	(1910)	75.1
Western Reserve University	(1910)	83.6
University of Pennsylvania	(1909)	77
Jefferson Medical College	(1909) 78.3; (1910)	80.9, 82.4

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Rush Medical College	(1892)	Illinois
Northwestern University Medical School	(1909)	Illinois
Louisville and Hospital Medical College	(1908)	Kentucky
University of Michigan, Dept. of Med. and Surg.	(1889)	Michigan
Albany Medical College	(1898)	New York
Jefferson Medical College	(1865)	Kentucky
Victoria University, Ontario	(1865)	Michigan

Wisconsin October Report

Dr. John M. Beffel, secretary of the Wisconsin State Board of Medical Examiners, reports that at the meeting held at LaCrosse, October 6, 1910, nineteen candidates were licensed through reciprocity and one by examination. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
College of Physicians and Surgeons, Chicago (1902) (2, 1903) (1908) Illinois	(1905)	Nebraska
Chicago College of Medicine and Surgery	(1909)	Illinois
Rush Medical College	(2, 1908)	Illinois
Northwestern University Medical School	(1907) (1909)	Illinois
Chicago Homeopathic Medical College	(1895)	Indiana
Medical College of Indiana	(1884)	Minnesota
University of Louisville	(1909)	Kentucky
University of Maryland	(1908)	Maryland

Marquette University	*(1909)*	78

Book Notices

AN INTRODUCTION TO THE STUDY OF HYPNOTISM, EXPERIMENTAL AND THERAPEUTIC. By H. E. Wingfield, M.A., M.D., B.C. Cantab., Consulting Physician Royal Hants County Hospital. Cloth. Price, $2. Pp. 175. New York: William Wood & Co., 1910.

A few years ago this little book would have been hailed with delight by both specialist and general practitioner. To-day, treatment by means of hypnosis is rarely resorted to by those best qualified to apply it. The great expectations attached to the study and practice of this fascinating method of treatment have failed of realization. The study of hypnotism has, nevertheless, been fruitful of results in the study and diagnosis of the neuroses. The entire field of psycho-analysis owes its revelations principally to hypnotism, though other methods have recently come into vogue. As a means of therapy hypnotism is but seldom practiced these days. Suggestion in the waking state, persuasion and mental reeducation have largely supplanted it. From the point of view of the therapeutist, the study of hypnotism has merely historical and educational values. For practical purposes, therefore, the book comes too late. To those who wish to begin the study of hypnotism the book can be recommended as a safe guide. The author is extremely conservative, has put forth no extravagant claims and has written a readable book. As stated by him in the preface, there is nothing new for those already familiar with the subject, but the book of about 175 pages is intended solely for those who as yet know nothing of hypnotism. To such inquirers it may prove of some service.

A TEXT-BOOK ON THE THERAPEUTIC ACTION OF LIGHT. Including the Rho Rays, Solar and Violet Rays, Electric Arc Light, The Light Cabinet. By Corydon E. Rogers, M.D. Cloth. Price, $3.50. Pp. 323, with illustrations. New York: C. E. Rogers, 382 Second Avenue, (1910).

This is a book which deals with the peculiar theories of the author in regard to the therapeutic action of certain rays of light which he calls "Rho" rays. The work hinges on "Rho" rays. But no adequate description of the "Rho" rays is given, and, in fact, no proof of any scientific value is furnished to establish their existence. In our humble opinion there are no such rays. The supposed rays are produced by a high candle-power incandescent lamp of the author's invention. This is an elaboration and an enlarged type of the therapeutic lamp with a parabolic or conical reflector of which the Rogers' therapeutic lamp of a few years ago (perhaps by the same inventor) was a type. The agent is recommended in almost all sorts of conditions from impetigo to optic atrophy. The work is entitled to no scientific consideration.

A TEXT-BOOK OF PHARMACOLOGY AND THERAPEUTICS. Or the Action of Drugs in Health and Disease. By Arthur R. Cushny, M.D., Professor of Pharmacology in the University of London. Fifth Edition. Cloth. Price, $3.75 net. Pp. 744, with 61 illustrations. Philadelphia: Lea & Febiger, 1910.

The necessity of a new edition of this text-book has led the author to make a thorough revision of the whole work. The decrease in the use of some of the minor remedies is noted and the space given to them is correspondingly reduced, some of them being entirely discarded. A chapter on antitoxins and their uses has been added. The investigations of recent years have made possible more positive statements regarding the action of some remedies and such groups as that of digitalis receive thorough treatment. New remedies receive appropriate notice. The new edition will continue to maintain the position of the work in the first rank among standard authorities on pharmacology.

THE IRON MUSE. By John C. Underwood. Cloth. Price, $1.25 net. Pp. 196. New York: G. P. Putnam's Sons, 1910.

A well named collection of virile verses. Here is a splendid thrill of vigorous combat with the world's various problems. Several of the poems have a medical bearing. "The Consulting Room" is a graphic picture from a layman's viewpoint. The cogent appeal in "The Real Thing," addressed to one who may think he is down and out, is a tonic, while, of quite another sort, "The Mirror" has a mystic tenderness, which by contrast with the majority of poems, shows the breadth of the author's feelings.

Medicolegal

Distinctions and Liabilities in Actions for Malpractice

The Court of Appeals of Kentucky says, in Randolph's Administrator vs. Snyder (129 S. W. R. 562), that William Randolph, a miner who had paid $1 a month for medical treatment for himself and family, first brought suit individually against the defendant physician for alleged refusal to come and treat his child, which had been badly burned and subsequently died. Then the said Randolph had himself appointed administrator of the child's estate and sought, by the amendment of his petition, to recover damages for the alleged negligent treatment of the case by the physician after he came and took charge of it.

If the physician made a contract with the plaintiff to treat him and his family, as alleged in the petition and amended petition, and simply broke the contract by refusing to come when sent for to undertake the case, the right of action would be simply for the breach of the contract, and there would be no right of action in tort, as it is called, which means for a wrongful act or alleged negligent treatment. But if the physician came and undertook the case, and, having undertaken it, was negligent in his treatment, then a cause of action in tort might be maintained for the non-performance of the duty which the law cast on him when he undertook to treat the case. The rule has often been applied in the case of innkeepers, carriers, attorneys, physicians, etc. They all rest on the same ground.

The plaintiff having finally elected to sue in tort must recover, if at all, on the latter ground. Moreover, while the administrator might recover for the pain and suffering of the child caused by the negligence of the physician, or for his death if caused thereby, he could not recover for both, and might be required to elect which he would sue for.

If an injury is inflicted by a physician negligently on his patient and death ensues therefrom he is liable for such death under the Kentucky statute, just as any other person would be whose negligence causes the death of another. Blackburn vs. Curd, 32 Ky. Law R. 789. In the case referred to the defendant operated on the patient, and then failed to give him the necessary treatment, by reason of which he died. It was held on those facts that the defendant was liable to the administrator of the patient's estate for the patient's death. In the case here before the court the physician did not operate on the child so far as was shown by the petition, but if he undertook to treat him, and negligently failed to give him proper treatment, this was an injury inflicted on him within the meaning of the statute, and if his death resulted from such negligence, the plaintiff might recover therefor. This case cannot be distinguished from the one cited. By section 6 of the Kentucky Statutes, which follows section 241 of the constitution, whenever the death of a person results from an injury inflicted by negligence or wrongful act, damages may be recovered therefor. The statute is remedial and should be liberally construed to effectuate its objects. The filing of the amended petition was in effect the bringing of a new suit, and an abandonment of the cause of action which had been stated in the original petition, and it should not have been allowed to be filed.

Releases Executed in Reliance on Statements made by Physicians

The Supreme Court of Minnesota holds, in the personal injury case of Nelson vs. Chicago & Northwestern Railroad Co. (126 N. W. R. 902), that a release of a claim for personal injuries, executed in reliance on fraudulent and false representations of probability of recovery, made to the injured person by an attending physician in the employ of persons sought to be charged therewith, is voidable. Such release may also be avoided when its execution is due to a mutual mistake of the injured person and of such a physician, who has assisted in procuring the settlement. The court says that the courts have generally viewed releases obtained by the physician, acting as assistant claim agent, with extreme suspicion, and in many cases in which the physician has acted in the dual capacity of claim agent and physician, or in which he has violated the proprieties of the situation and has expressed his opinion with reference to or in connection with a settlement then pending, the courts have avoided releases on the ground of mutual mistake, where subsequent experience has shown that the physician was in fact wrong. But it does not at all follow that in every case wherein there is a subsequent discovery of mutual mistake made by the defendant's physician as to the subsequent course of the plaintiff's injury, that a release executed after the mistake has been made is void. Into which class a particular case under consideration should properly fall must depend on its peculiar circumstances. Where an attending physician in the course of treatment expresses a mistaken, but honest, opinion as to the period within which the injured person, suffering from a known injury, would recover, and where that expression of opinion, when made had no connection whatever with a settlement or with negotiations for a settlement, a release executed in reliance on his statement, may in certain cases properly be held valid.

MINNESOTA STATE MEDICAL ASSOCIATION

Annual Meeting held at Minneapolis, Oct. 6-7, 1910

The President, Dr. W. A. Jones, Minneapolis, in the Chair

Address of the President: The State Medical Association and Its Relationship to the Problems of the Day

Dr. W. A. Jones, Minneapolis: The first problem suggested for consideration is how to secure a live interest and discussion on the yearly program. The men in the country are either over-modest or indifferent, and the burden of preparing papers falls on a few men from the chief cities in the state. The man in the country is often a man of ideas gleaned from hard earned experience and worked out without assistance, and the busiest man is the man who usually finds time for literary work outside of the hours devoted to practice.

Another problem is suggested by the inability of medical men, organized into associations or societies, to secure the creation of a national department of health. This is an illustration of the need of further systematic effort to impress legislators and congressmen with the necessity of safeguarding the public health. The opposition to this movement is composed of a cosmopolitan crowd, who fear restraint or loss of their illegal means of livelihood by the manufacture and sale of fraudulent remedies, nostrums or appliances. It is further supplemented by narrow minded people, who through ignorance or superstition exploit the new fads and cults incidental to the century, including opposition to vaccination, vivisection and other methods of advancing scientific information. The national and local League of Medical Freedom, supported by a few sensational newspapers is striving to arouse public sentiment against medical sanitary and hygienic progress. In spite of this opposition, a campaign of education by medical men must go on relentlessly. Much good has already been accomplished by the exposure of fraudulent remedies and fakers, who live on the misfortunes of the sick. The greatest difficulty is to get this information before the laymen. Physicians know of these frauds, but cannot always present proofs to their patients. The only remedy lies in the education of the masses to separate the good from the bad.

I strongly urge the employment of a journalist, who will acquaint himself with the fundamental needs of the people as advocated by physicians, and who will use his journalistic attainments and become a medical press agent. As physicians, we must learn to attend strictly to our own professional work and suspend personal abuse of fakers and newspapers until we have the confidence of the people and the press. Legislators should enact laws for the protection of the sick against cults, charlatans and nostrums. Indecisive fear on the part of the law maker is responsible for the present unenviable condition that so widely prevails.

All departments in the state which have to do with public health measures should be asked to send representatives to confer with a legislative committee composed of representatives from the state medical association, the board of health, the university alumni and the sanitary conference. The members of the Minnesota State Medical Association should take more active interest in and familiarize themselves with the work of the state hospitals and institutions. The medical school of the state university deserves the support of all of Minnesota's medical men.

Case of Metastatic Gonorrheal Conjunctivitis

Dr. William R. Murray, Minneapolis. This was a case of a simultaneous bilateral conjunctivitis occurring in a patient the subject of gonorrhea. There was no involvement of the intraocular structures. The lids were considerably swollen, there was a moderate conjunctival discharge, the bulbar conjunctiva was edematous, and an arthritis of the wrist joint accompanied the conjunctivitis. The first attack of conjunctivitis lasted ten days and subsided and after an interval of several days was followed by a second attack of conjunctivitis, involving both eyes, which was also attended by an arthritis. There was no intraocular involvement during either attack of conjunctivitis. No gonococci could be found in the conjunctival discharge. A diagnosis of the metastatic origin of a gonorrheal conjunctivitis is based on the bilateral involvement of the eyes, moderate amount of discharge, slight swelling of the lids, chemosis of the bulbar conjunctiva, comparative mild course of the disease, tendency to recur, absence of gonococci in the conjunctival discharge, and evidence of a systemic gonorrhea.

Dr. C. D. Conkey, Duluth: The case reported by Dr. Murray must have been of a metastatic nature, for microscopic examinations of the eye secretions were frequently made all through the attack without discovery of gonococci. The method of infection is probably by the direct entrance of the gonococci into the blood stream from the urethral tract. I have under my care at present a case of gonorrheal iritis with an arthritis of the right knee in which I administered three injections, two of 25 000 000 and one of 50 000 000 gonococci. The larger dose was followed by a decided reaction, the malaise lasting for several days, the joint affection being decidedly bettered, but no effect was produced on the inflamed eye.

The Heart in Diseases of the Thyroid

Dr. J. S. Gilfillan, St. Paul: That a relationship existed between the thyroid and the heart has long been known. The credit, however, for bringing the subject prominently before the profession belongs to Professor Rose who, in 1877, read before the German Surgical Congress a paper in which he established the influence of tracheal obstruction on the right heart.

Since a paper in 1899 by Professor Kraus it has been generally conceded that, aside from any respiratory obstruction, the thyroid may produce cardiac changes through certain toxic influences. Goiter heart may be classified as mechanical, or Rose's heart, and toxic, or the goiter heart of Kraus.

The symptoms of the mechanical variety are those of dilatation and insufficiency of the right heart in addition to those of tracheal obstruction. This form of cardiac disease is not peculiar to goiter but may be produced by pressure by any tumor.

The type of heart described by Kraus is produced by the altered or increased secretion of the thyroid acting on the regulatory mechanism. This may occur in any form of goiter. Symptoms consist in strong and rapid heart action, with at times other evidences of hyperthyroidism. In many cases there is enlargement of the left ventricle, which can be seen with the fluoroscope to be due to an increased diastolic distention Kraus tries to draw a distinct line between these cases and Basedow's disease. Kocher includes in the same class all cases presenting symptoms of thyroid intoxication Cardiac symptoms are very common in goiter patients Monnier found 25 per cent showing distinct heart symptoms Kocher calls attention to the fact that during or after the administration of iodin in any form for goiter, symptoms of thyroid intoxication may develop, due to hypersecretion of the gland stimulated by the iodin In goiter heart the ordinary heart remedies are of but little value Iodin should be used with great care if at all Toxic cases may be treated with rest, diet, sodium phosphate, etc but here as in mechanical cases operation should not be too long deferred.

Intraspinal Injections of Magnesium Sulphate in Tetanus

Dr Carl J. Holman, Mankato Two cases of tetanus were treated by magnesium sulphate injection One came on nine or ten days after a crushing injury to the ring and middle fingers of the left hand, necessitating amputation The symptoms of tetanus developed about the tenth day and the patient was given two doses of magnesium sulphate into the spinal canal, dying four hours after the last dose Case 2 was an appendiceal abscess The patient developed tetanus on the eleventh or twelfth day after the operation and received in all twenty-five doses of magnesium sulphate into the spinal canal He made a good recovery and is now well, performing farm labor.

(To be continued)

IDAHO STATE MEDICAL ASSOCIATION

Eighteenth Annual Meeting, Held at Boise, Oct 6 7, 1910

The President, Dr John M Taylor, Boise, in the Chair

Hon J T Pence, Mayor of Boise, made an address of welcome, which was responded to by Dr J. L Stewart of Boise

Officers Elected

The following officers were elected for the ensuing year president, Dr John W Givens, Orofino, vice president, Dr George O A Kellogg, Nampa, chairman committee on arrangements, Dr J W Gue, Caldwell, chairman committee on legislation, Dr J M Taylor, Boise, chairman committee on nominations, Dr J C Woodward, Fayette, chairman committee on public health, Dr G H Coulthard, Idaho Falls, trustees for *Northwest Medicine*, Dr R L Nourse, Boise (reelected), Dr J W Givens, Orofino (reelected), and Dr W T Drysdale, New Plymouth, delegate to American Medical Association, Dr A A Higgs, Boise, alternate, Dr C L Dutton, Meridian

Boise was selected as the place of the next meeting.

President's Address Principles in Etiology and Treatment of Disease

Dr John M Taylor, Boise, read his annual address on the above subject

DISCUSSION

Dr W T Williamson, Portland The profession has done much in developing the study of medical subjects among the laity Public education along the lines of personal hygiene and unhealthful habits is of great importance Physicians must reach the young through the teachers in the schools A competent member of the profession should be in attendance at all gatherings of teachers and lose no opportunity of instilling these thoughts into their minds

Dr George E Hyde, Rexburg It is evident to all that we are getting away from the era of superstition, medicine, through education, is less a mystery.

Spinal Anesthesia

Dr C C Snyder, Salt Lake City I have confined the use of spinal anesthesia to cases in which a general anesthetic was unsuitable With the use of strychnin and atropin in connection with the spinal injections, there seemed to be less headache and nausea following I prefer tropacocain to other cocain preparations, but it does not act so well above the diaphragm as does the hydrochlorate of cocain In my experience the chief contra indication to spinal anesthesia is a possible idiosyncrasy to the drug

DISCUSSION

Dr A E Rockey, Portland In a series of 25 or 30 cases in which I used cocain, I had 2 cases of anuria Subsequently I used tropacocain in about an equal number of cases, and found it to be safer, but it did not seem so active as an anesthetic

Surgery of the Large Intestines

Dr A E Rockey, Portland, read this paper

DISCUSSION

Dr E K Scott, Boise Very few cases of malignant disease of the lower bowel are seen early enough to justify resection I have seen many such operations, and know of but one case in which satisfactory results followed resection for malignant disease In spite of the objectionable features of colotomy, I prefer to advise it in advanced cases In treatment of colitis, irrigations and local treatment through the rectum can be done more easily and with the same good results as Dr Rockey reports from appendicostomy

Dr J L Stewart, Boise I have done several resections for malignant disease of large bowel, I agree with Dr Scott in believing that resection in these cases, unless the growth is low down, is not usually satisfactory

Dr J M Taylor, Boise Which incision does Dr Rockey consider most advantageous, and would ptosis of the abdominal organs complicate the operation?

Dr A E Rockey, Portland The remarks of Dr Scott refer more to the older methods of operating By the newer methods, posterior incision, removal of coccyx, etc, I have found it easy to get room for removal of the tumor and to bring the bowel down Prolapse of the sigmoid does not complicate the technic, if anything, it makes it easier I have been using the transverse incision for some time in all appendectomies, and only through accident discovered its advantages in exposing the large bowel

Important Facts Concerning Myopia in Children

Dr Edward E Maxey, Boise, read this paper.

DISCUSSION

Dr R L Nourse, Boise Myopia is one of the penalties of civilization Aborigines are not myopic Students and those who apply their eyes closely for near work are apt to become myopic Unless astigmatic, low degrees of myopia do not need glasses for comfort, as is often the case in low degrees of hyperopia, hence they are often undetected until fairly well advanced

Dr W T Williamson, Portland There are a considerable number of nervous conditions caused by errors of refraction, especially in school children For various reasons, school inspection is of vital importance to the child, especially inspection into the condition of the eyes, and, it is needless to say, these examinations should be made by competent men and repeated at frequent intervals

Dr E Van Note, Boise In the examination of children's eyes we should emphasize the tendency myopia has of progressing, as very few parents understand its seriousness

Dr J W Givens, Orofino In almost all forms of insanity very little help is to be had by correcting defects of vision However, the relation of errors of refraction to headaches should be constantly kept in mind in treating mental conditions

Dr E E Maxey, Boise Children of myopic parents are predisposed to myopia Such children, after they reach the school age, should be examined once or twice a year Low degrees of myopia, especially if astigmatic, should be fully corrected and glasses changed as often as necessary. All examinations and reexaminations should be made under a reliable mydriatic, preferably atropin If the myopia is progressing in spite of proper glasses, the child should be taken out of school and near work materially curtailed or prohibited entirely.

Application of Modern Methods in the Early Diagnosis of Pulmonary Tuberculosis

Dr. Ray W. Matson, Portland: A continuous afternoon fever is always suspicious of tuberculosis, and I have invariably found a material rise in temperature after exercise which was a little higher and remained longer than in the absence of tuberculosis. The tuberculin test in the human being is exactly the same and just as reliable as it is in cattle. Both von Pirquet's and the subcutaneous methods of using tuberculin give a positive reaction in the presence of an active or a healed lesion, while the eye test, being less sensitive, gives a positive reaction only when an active lesion is present. Therefore if the physical examination, the *x*-ray and laboratory findings lead us to believe that an active lesion is present, the tuberculin test should be applied by either von Pirquet's method (preferably) or subcutaneously. In all my examinations, the physical and laboratory findings are invariably controlled by *x*-ray examination.

DISCUSSION

Dr. R. C. Faust, Deary: Recently I heard of a new sign of incipient tuberculosis, *viz.*, that if the temperature be taken before and after examining the patient we would find a rise of from 1 to 1.5 degrees F. at the conclusion of the examination, but I am not prepared to express an opinion as to the value of this sign.

Dr. J. M. Taylor, Boise: The early diagnosis of this condition depends in a great measure on the experience and delicate technic of the examiner.

The Recent Epidemic of Infantile Paralysis

Dr. W. T. Williamson, Portland, delivered an extemporaneous talk more particularly to the laity, many of whom were present to hear him.

While the disease has been known to exist for the last forty years, it is only within three years, or even one year, that much has been learned about it. That the cause is a living organism is positive, but it is so small that it has not yet been discovered by the microscope. Experiments have been made on various animals, the only two responding to injections of blood containing the poisons of this disease being sheep and monkeys, the former in a very mild degree, while the latter proved so susceptible that many experiments have been made on them, but nothing definite by way of a solution has yet resulted, the inoculation in some instances, but not all, making the animal immune. The early symptoms presented marked differences from other infectious diseases; three symptoms which usually accompanied the disease are increased perspiration in children, great sensitiveness to touch, and change in the number of white blood cells. As remedies for the disease may be suggested calomel followed by hot water enemas, and hot external applications for the pain. I would advise against allowing a child suffering from this disease to lie on the back, as this position is apt to aid in producing congestion of the spinal cord and thus may increase the severity of the resulting paralysis. While we can not yet cure the disease, we can do much in preventing deformity. Treatments should be kept up for years, if necessary, and by so doing much of the deformity, if not all, can be eliminated. Rest both during and after the disease must be insisted on in order to prevent paralysis.

DISCUSSION

Dr. Ralph Falk, Boise, secretary of the State Board of Health: The Board of Health has thought it advisable to consider this disease of sufficient virulence to require reporting and quarantine, and the length of quarantine has been fixed at three weeks. By the end of this month there will probably be at least 100 cases of this mysterious disease reported in Idaho, 57 cases having already been reported. Most of these cases are in Idaho County, and they have been investigated personally by Dr. Hyde, president of the board.

Dr. George E. Hyde, Rexburg, president of the State Board of Health: In investigating the cases in Idaho County, I found most among the Germans. In from 60 to 70 per cent. of the cases, obstinate constipation was present, and the acute symptoms almost invariably subsided on removing the constipation. Fourteen of the cases were abortive, 5 patients died, and 30 per cent. developed paralysis in the left leg, these usually recovering. The disease occurs during the hot, dry season, the dust apparently irritating the nasopharyngeal mucous membranes and thus enabling the virus to enter the system. The period of incubation is from four to sixteen days. I have been able to determine that 14 of the patients contracted the disease by direct infection, while in 12 cases the infectious material had been carried by a third person. As prophylactic measures, the board has recommended quarantine for 3 weeks and the frequent use of antiseptic washes for the nose and mouth.

Dr. C. F. Eikenbary, Spokane, Wash.: There could hardly be any doubt as to the contagious nature of this disease, yet we find occasional sporadic cases. In this recent epidemic, it seemed that the child was sick longer than usual before paralysis developed, and this would seem to suggest the possible prevention of paralysis. It is important to prevent deformity of paralyzed limbs by the use of splints.

[The splint or brace mentioned by Dr. Eikenbary is made of stockinette or some such woven material, saturated with celluloid. The celluloid is prepared by dissolving small pieces of celluloid in commercial acetone until a solution the consistency of mucilage is obtained. A plaster cast is made of the limb or part of the body where the splint or brace is to be worn. When this is prepared, the stockinette is stretched over the cast and plastered with the celluloid paste, then another layer of stockinette is added plastered with celluloid paste, and so on until the desired thickness is obtained. To prevent curling and wrinkling, the splint is left on the cast for one week or until thoroughly dry. The splint is then cut from the cast, trimmed to desired shape and size, and the edges bound to make them smooth.]

Dr. J. W. Givens, Orofino: Climatic and atmospheric conditions have much to do in lowering the vitality of children. Children should not be exposed unnecessarily. They should be kept off the damp ground or grass in the evenings. As an intestinal cleansing agent, the old fashioned Epsom salts are excellent, given in small doses three times a day.

Dr. J. A. Pettit, Portland: Our greatest work should be along the line of investigating and determining the cause. The nasal theory appears to me to be rather overdrawn. The brain is not affected in infantile paralysis at all, yet if the infection gains entrance through the nasal mucous membrane one would naturally expect extension by continuity of tissues to the brain or its membranes. The spinal cord is affected and the paralysis shows that the diseased condition never extends higher than the motor cells of the fourth ventricle.

Dr. L. P. McCalla, Boise: The profession should use greater moderation in discussing this disease, and consider the evil effects of unnecessarily alarming the public. The fear and dread of this disease is worse on the mothers of children than the disease itself. Many of these so-called abortive cases are not infantile paralysis at all, but cases of auto-intoxication due to gastro-intestinal disturbances. But granting that all of the cases reported are infantile paralysis, the disease is no more severe than whooping cough, and we do not think that serious enough either to report or to quarantine. The disease may be infectious but it is not proved to be contagious, and I think that the profession should frown down the newspaper notoriety recently given to this disease.

Dr. Ray W. Matson, Portland: Predisposition to disease in general is a probable important factor in the causation of this disease. The germs of various diseases are constantly present in the mouths and noses of most of us, but being more or less immune to these organisms we are not affected by them. We have not yet been able to determine the specific organism of infantile paralysis because the organism of this disease is what we term ultramicroscopic, like that of scarlet fever, and, therefore, invisible to present methods of examination.

DR. W. T. DRYSDALE, New Plymouth: In view of the extensive publicity given this disease and the doubtful prognosis in the cases reported, the State Board of Health should be commended for the position it has taken in the matter of quarantine.

DR. E. VAN NOTE, Boise: Some diseases increase in virulence, while others decrease, as in the case of small-pox. Have we the same old active poliomyelitis, or is it less active; and, if less active, will it remain so? Flexner's experiments seem to show that the virulence of this disease is increased by transmission in the monkey, so we may have the disease worse than now, and it is our duty to watch for this increase in virulence.

DR. G. E. HYDE, Rexburg: I do not believe in scaring people over trivial matters, but the condition existing in Idaho County, where in one district 10 per cent. of the children are ill with this disease, is no longer a trivial matter.

MR. EDGAR WILSON, Boise: From a layman's point of view, and from my experience as a member of school boards, I would like to endorse the remarks made by Dr. McCalla. I regret the tendency of newspapers to "scare-head" these health conditions. It can do no good, and often does a real harm. Public health matters are and have been very well handled.

DR. C. L. DUTTON, Meridian: It is not impossible for this condition to be due to more than a single specific infection. The state board is right in trying to prevent extension of this disease.

DR. W. T. WILLIAMSON, Portland: It is easy to believe that we have been having sporadic cases of this disease, caused by some different form of infection, but these are probably not due to the same cause as the epidemic cases. Flies, mosquitoes, and other insects, are possible carriers of the disease. The treatment must be begun early, for if the disease is allowed to progress we soon have what might be called "an organized disorganization," producing permanent lesions. The tendency of epidemics is to regress or diminish in severity, and we are not justified in expecting an increase in virulence of this disease simply because inoculation of monkeys produced a disease of increased virulence. It is hard to collect evidence of the contagiousness of a disease when we do not know the cause. Therefore, we should uphold the health boards in the matter of quarantine, until such time as we can determine the true specific cause.

Surgical Treatment of Cancer of the Prostate

DR. GEORGE S. WHITESIDE, Portland, read this article.

DISCUSSION

DR. A. A. HIGGS, Gooding: Early diagnosis is of importance in these cases if operation is to be of any value. If a case is at all suspicious of cancer, the patient should be referred early to a competent specialist for diagnosis and treatment.

DR. A. E. ROCKEY, Portland: I have done Young's operation for cancer and think it a splendid method, but I prefer to combine it with suprapubic incision. In most simple enucleations of prostate I prefer the suprapubic route.

DR. G. WHITESIDE, Portland: Suprapubic incision is not necessary, as the bladder is very easily brought forward. Hemorrhage is not a prominent symptom in early cancer. If present it is frequently due to irritation from catheterization. Success of operation depends on attention to thorough asepsis, both before and after operation, and the use of continuous irrigation for several days after.

DR. L. P. MCCALLA, Boise: Metastasis to the bones frequently occurs in cancer of prostate, and metastasis of cancer of the thyroid to the prostate is not uncommon. In regard to method of operating, each operator develops a technic of his own which for him is best. For five years I have used continuous irrigation with excellent results except in one case.

DR. H. GOODFRIEND, Albion: On the pathologic examination of several hundred cases of diseased prostate, about 2 per cent. of the specimens in one series were found to be malignant, while in a second series from another operator about 6 per cent. were malignant.

DR. G. WHITESIDE, Portland: I am familiar with the figures just given and the claims made by certain operators, but I think that 10 per cent. is nearer the right figure of percentage for malignant cases.

Tubal Pregnancy

DR. J. A. PETTIT, Portland, read this paper.

DISCUSSION

DR. W. T. DRYSDALE: Is it advisable to postpone operation until after recovery from shock? In my opinion there is a considerable percentage of patients who do not die from the initial hemorrhage and shock, and most of them have a better chance for ultimate recovery if we wait until after recovery from shock before operating.

DR. L. P. MCCALLA, Boise: It is important to diagnose these cases early and to be prepared for the impending trouble. Most of these patients give a history of former pelvic inflammation and irregularity of menstruation, usually being from 2 to 10 days over-time rather than under-time. If gestation is located near the uterus we can usually find decidual membrane if the microscope is used. The pain is different in character from any the patient has before experienced. The best time to operate depends on the case, but not all patients should be operated on without preparation or recovery from shock. When it is possible to do so, these patients should be referred to an experienced surgeon. It is unusual for them to die if not operated on during profound prostration of shock. The points of especial assistance in making an early diagnosis are: (1) a history of past pelvic inflammation; (2) irregular menstruation, usually going overtime; (3) difference in type of pain, and (4) mucous type of discharge, often containing decidual cells.

DR. G. WHITESIDE, Portland: It is very interesting to me, as a genito-urinary specialist, to learn that human spermatozoa might remain active in the tube for as long as 3 weeks, and that the bat's spermatozoa might remain active for 6 months. It is interesting, also, to think of the possible medicolegal complications that might arise from these facts.

DR. VAN NOTE, Boise: It is usually taught that operation should be done in these cases of extra-uterine pregnancy as early as possible, but we often lose sight of the fact that the shock stops the hemorrhage. However, the hemorrhage is apt to recur on revival of the patient, and beginning of the recurrence would appear to be the ideal time for operation.

DR. G. H. COULTHARD, Idaho Falls: All these patients should be operated on as soon and as quickly as possible, clamps being used if necessary, and left on until it is safe to remove them.

DR. L. P. MCCALLA, Boise: I do not wish to be misunderstood as to my position in the matter of time to operate. A reason for postponing operation is the frequent unpreparedness in these cases, with lack of proper hospital facilities and skill in operating. Personally, I operate in all cases, but I probably have better advantages than the physician who sees his case in the country. It is safer to wait for proper preparation than to undertake an operation like this under improper surroundings and without proper preparation.

DR. J. A. PETTIT, Portland: I always operate as soon as a patient can be removed to hospital, as I have found that the operation itself causes no shock. It is the hemorrhage that causes death. Tubes that bleed freely are easy to remove or tie off, as they are not bound down by adhesions, and we must remember too that shock does not always stop the hemorrhage. I know of no way of estimating the percentage of these patients who would recover without operation, and it is also so difficult to diagnose the presence of a decidua vera that it is hard to say what size it might become.

Diagnosis and Treatment of Certain Hip-Joint Diseases

DR. C. F. EIKENBARY, Spokane, read this paper.

DISCUSSION

DR. L. P. MCCALLA, Boise: I am surprised to learn that many of these fractures occurred in younger people, as I have been of the impression that most of them were in old women.

Breaking up the adhesions under anesthesia is of great importance in securing a useful limb I use the *x* ray in these and all other fracture cases as a routine practice

Dr E Van Note I have obtained considerable assistance in determining the amount of tilting of the pelvis by placing a yardstick or rule across the pelvis on the anterior superior spinous processes

Dr W. R Drysdale We frequently are in doubt for some time as to whether or not a fracture is really present, and, in my opinion, such cases should be treated as fractures until we are sure of diagnosis

Dr Eikenbary We should not depend too much on the *x* ray findings as they may lead to error The length of time that hip joint disease should be treated must necessarily differ in different cases, but it should usually cover a period of from 2 to 3 or more years

Hygienic Laboratory for State Board of Health

Dr Ralph Falk, secretary of Idaho State Board of Health read a report on the needs the state had for such a laboratory, and asked the association to endorse the board's petition to the legislature, asking for a sufficient appropriation to equip and maintain such a laboratory

After considerable favorable comment on the advantages to be derived from such a laboratory, the association, on motion of Dr E W Kleinman, endorsed the plan for a state hygienic laboratory and unanimously joined with the State Board of Health in asking the legislature to appropriate sufficient money for its maintenance in an efficient and practical manner

INDIANA STATE MEDICAL ASSOCIATION

Annual Meeting held at Fort Wayne, Sept 18 30 1910

(Continued from page 1759)

Rabies—History and Treatment

Drs H S Thurston and H R McKinstry, Indianapolis Rabies was known as far back as the time of Aristotle, and was described by Galen and Celsus In Berlin, rabies was common prior to 1875 Since then a law has been enforced requiring the killing of dogs suspected of rabies, and the muzzling and leading of dogs when in public places There have been no cases of rabies there since 1883 Previous to Pasteur's work treatment was ineffective The method I follow is Pasteur's with the Calmette modification In my opinion the muzzling of all dogs will prevent 90 per cent of human rabies As a result of the Pasteur treatment, in 26 000 patients treated in Paris from 1886 to 1901, less than 1 per cent died from hydrophobia A similar ratio is shown in New York and other places

DISCUSSION

Dr J P Simonds, Indianapolis Rabies or hydrophobia is in many ways one of the most peculiar diseases known It is classed among the infectious diseases but there is probably no other infection in which the incubation period is so variable in which so few persons (probably not more than 10 per cent) inoculated with the virus actually develop the disease, and which is so uniformly fatal when once the symptoms have appeared Of recent work on this perplexing disease, that of Paltauf is the most enlightening He had the rare opportunity to perform autopsies on seven persons who had been bitten by rabid dogs, but died of some other cause. Four of these had not taken Pasteur treatment Although they had shown no symptom of hydrophobia up to the time of their sudden deaths, their brains were proved to contain the rabic virus by the production of the disease in rabbits inoculated with them The other three had taken Pasteur treatment and their brains were not virulent for rabbits Paltauf's conclusions were that in infected persons the virus usually reached the brain and cord only to be destroyed there in nine cases out of ten, by the natural protective mechanism of the body The institution of Pasteur treatment merely rendered this natural defensive mechanism more effective. It is now less than ten years since Negri discovered certain granular 'bodies' in the brain cells of infected animals, and thus made possible a quick and accurate diagnosis of this disease There has been much dispute as to the real nature of these 'Negri bodies" and at least four theories have been advanced to explain them Negri and others believe that they are protozoa, belonging to the microsporidia, and that they are the immediate cause of the disease They base this conclusion on the internal structure and staining properties of the bodies The specificity of these bodies for rabies is now generally accepted Pool collected the statistics from six European laboratories in which the microscopic examination of 550 dogs' brains had been controlled by animal inoculation. In 334, Negri bodies were found, and all the guinea pigs inoculated with these brains developed rabies In the remaining 206 cases, no Negri bodies were found but eleven guinea-pigs injected with these brains developed the disease Hence this general principle has come to be accepted as expressing the truth: The finding of Negri bodies in a brain may be accepted as positive proof that the animal had rabies, but failure to find them does not prove absolutely that the animal was free from the disease During the last 4 years an extensive epidemic of rabies has existed in Indiana At the Indiana State Laboratory during this time the brains of 376 animals have been examined and of these 213 or 56 6 per cent showed positive evidence of rabies This by no means represents the actual number of cases of the disease for many animals known to have been infected die of the disease and their heads are not sent to the laboratory at all Our method of diagnosis is as follows Stained smears from Ammon's horn and the cerebellar cortex are examined for Negri bodies If these are found the case is pronounced positive at once If Negri bodies are not found and the dog has bitten some human being a guinea pig is injected subdurally with an emulsion of the brain It has been only a very rare occurrence that the guinea pig test has proved positive when no Negri bodies were found with the microscope

It is impossible to measure accurately the amount of damage done in this state by rabid animals Our records show that 165 persons have been bitten, but this probably does not represent half the actual number The loss of live stock has been very great A dairyman at Richmond lost fourteen fine milk cows as the result of the ravages of one dog Similar stories of large individual loss have come from other parts of the state Early this year there were indications that the epidemic was abating But since May a large number of cases have developed in territory hitherto free from the disease In the north central part of the state there is a newly infected district, including Howard, Carroll Tippecanoe and Benton counties the chief foci being about Kokomo and Lafayette In the south central portion is another strip of recently infected territory, extending from Wayne county southwest through Fayette, Rush, Shelby and Decatur counties At present the outlook for subsidence of the infection is not very promising

Dr Ellen Knabe Indianapolis Those who have followed the work of the Indiana State Laboratory through the last five years especially since 1906, will know that everything has been tried to eradicate this epidemic of rabies In 1905, especially, the epidemic was widespread Few portions of the state did not suffer damage on account of it

Those who have stood, as I have, at the death bed of a person dying from hydrophobia, will never forget it Usually the greatest trouble is with the people who believe that everyone's dog is liable to harbor the infection except their own. Occasionally a community will pass a muzzling order Muzzling is the only way to stop the spread of this infection; but my experience has been that such laws are very imperfectly enforced, and that enforcement is not persisted in long enough to do any good These sporadic efforts, however, are of no value Any measure to be effective must be state wide There must be no place where the dogs are not muzzled Half our measures are worse than none at all, and only tend to bring into discredit the only method which brings any results if persisted in If we would only muzzle every dog that is worth the cost of a muzzle, and destroy all the rest we could soon get rid of the infection, but at the end of a year or two, were we to relax our vigor the infection would soon be carried all through the state again.

Fracture of the Patella

Dr Paul J Barcus, Crawfordsville Fractures of the patella constitute 1 4 per cent of all fractures, and this bone is refractured more frequently than any other, 88 per cent of these fractures occur in males, most frequently between the ages of 30 and 50 They are caused by direct violence, such as a gunshot wound or a fall or blow on the knee, or by indirect violence—muscular strain The relative frequency of these causes is a matter on which there is the widest difference of opinion The treatment is operative and nonoperative. Non operative treatment is limited to cases in which operative treatment is contra indicated The time of operation is a subject of debate The tendency at present is to wait five or seven days after the injury before operating in order to permit the joint to acquire a certain degree of immunity that follows a hemorrhage into the joint, and to permit swelling and immediate reaction in a measure to subside In an ordinary case if seen early, I can see no good reason for delaying operation beyond a few hours Indeed, delay is an acknowledgment of lack of confidence in our surgical technic and delay protracts convalescence the number of days delayed The institution of passive motion at as early a date as possible, massage and careful use of the knee, are of the greatest importance in the after care

DISCUSSION

Dr H R Allen, Indianapolis In repairing these cases it is important to run the purse string suture close to the patella—to get as close to the bone as possible If this is not done there will be limitation of motion

Silk or linen sutures lubricated with petrolatum should never be used They will not hold Wire should be used My preference is medium soft steel wire polished bright and sterilized The patient should lie flexed at the hips, in order to relax the tension of the extensor muscles I do not use plaster of Paris, I prefer wire splints, because they are easily removed to permit inspection In order to avoid adhesion begin passive motion at the end of the first week Begin flexion later on Be sure by the time the fibroid structure is established that motion has been established, at the best you can do, not all of your cases will come out perfect

(To be continued)

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

Sixtieth Annual Meeting, held at Pittsburg, Oct 3 6, 1910

(Concluded from page 1758)

Oration on Surgery Surgery, Past, Present and Future

Dr John B Deaver, Philadelphia If we pause at any moment to assess the present or gaze into the future, our safest guide is a knowledge of the past Every race in every age has flattered itself that it was the true age of progress and believed that the like could never be seen again The surest antidote to such complacency is to realize how often this has proved false in the past The surgery of the past was notable chiefly for the establishment of a few underlying principles on which all our modern practice is based For centuries men were content to have pus and even praised it if it were of that consistency and character which was thought proper. Then, as now, the object of the surgeon was to get his patient well, and he gave less thought to originating epoch making innovations applicable to all surgery than to the individual problem presented by his patient It was accordingly only after ages of groping among details that principles began to emerge. The period did not lack for men of boldness and ingenuity, but they suffered from a lack of these underlying essentials of successful surgery.

The present era of surgery dates from the discovery of anesthesia by Morton and the practical recognition by Lister of Pasteur's discoveries. The surgery of the present is remarkable for the elaboration of method and technic and the rise of surgical pathology With the introduction of new methods surgery found its main field in the body cavities, regions previously secure from entrance Also operations for cancer and on the vascular system have been vastly improved Abdominal surgery has been opened up as a new field The surgery of the pylorus and the pancreas is being rapidly developed Dyspepsia has been found to rest usually on an organic basis The surgery of the pelvic organs and the genito urinary tract has reached a plane of efficiency where it waits on improvement in diagnosis and early reference of patients The surgery of the head has advanced *pari passu*, it responds to the same principle as in surgery elsewhere The surgery of the thoracic cavity has lagged behind on account of the difficulties of practical application of surgical principles This problem belongs to the future The treatment of infections will be greatly aided in the future by serums and vaccination As yet, the early application of the aseptic scalpel reigns supreme in the cure of tumors benign and malignant Every tumor especially of the breast, uterus or stomach, should be considered malignant until proved benign

Pathology and Treatment of Acute Bone and Joint Infections

Dr J B Murphy, Chicago. Ankylosis of joints occurs only where the bony surfaces come into contact Therefore, in acute joint affections to prevent ankylosis extension should be put on Tension must be relieved, not by incision, as that leads to obliteration of the cavity, but by aspiration Following aspiration there is injected into the joint a 2 per cent dilution of liquor formaldehydi in glycerin In acute osteomyelitis in order to prevent destruction of the bone, it is essential to relieve pressure at once This the physician can do with a knife and an ordinary gimlet In case the bone is destroyed it can be restored by transplanting

Acute Dilatation of the Stomach: Report of a Remarkable Case

Dr. E Laplace Philadelphia Acute dilatation of the stomach is very fatal 63 5 per cent of individuals so affected dying It is not so rare as the literature leads us to believe This is shown by the rapid increase in the number of cases reported since the subject has become better known The stomach tube is the immediate remedy When, however, the condition is more accentuated, a large gastro enterostomy should be performed to drain the stomach effectually and permanently The rarity of this condition should be no excuse for our overlooking its possible existence in a given case, for an early diagnosis, followed by washing out the stomach might prevent a condition which otherwise would prove fatal in a few hours

Chronic Gastroduodenal Dilatation

Dr G P Muller, Philadelphia The etiology of postoperative dilatation of the stomach is still obscure, dilatation of the stomach being considered by some as primary and by others as secondary to compression or kinking of the duodenum The chronic type has been reported in only a few instances, but may have a similar etiology

Discussion on Dilatation of the Stomach

Dr John H Musser, Philadelphia The only case of dilatation of the stomach I have seen was one that appeared to be due to defective innervation I have been on the lookout for gastroduodenal dilatation, but I must confess that I cannot during life make the diagnosis of the condition

Diffuse and General Peritonitis

Dr John J Buchanan, Pittsburg The best treatment of peritonitis is its prevention The bulk of cases are usually the result of perforative appendicitis and can be prevented by removal of the appendix within a few hours or a day of access of the first pains Purgation is the most deadly medication that can be employed in acute appendicitis or diffuse peritonitis Immediate operation, or at least during the first twenty-four hours, dry mopping and closure of abdomen without drainage can be relied on to effect a cure in almost every case of free, diffuse or spreading peritonitis from perforative appendicitis. Treatment by irrigation is disseminative of septic products and should not be employed. Even the earliest operations cannot yet be relied on to check the spread of peritonitis from perforated gastric ulcer, and in these cases the delay of a few hours may mean death for the patient.

Dr. J. B. Murphy, Chicago: I have had sixty-four consecutive cases of perforative peritonitis with sixty-two recoveries. This does not include the appendiceal abscesses or appendicitis cases with large quantities of pus that did not communicate directly from the alimentary tract into the free peritoneal cavity. I feel that we as a profession must come up to the standard that all cases of appendiceal peritonitis with the exception of 1 per cent. of primary perforations are avoidable. The diagnosis can and should be made before the perforation.

Diagnosis of Duodenal Ulcer; Indications for Operative Intervention

Dr. J. H. Gibbon, Philadelphia: The pain of duodenal ulcer comes on in from two to four hours after ingestion of food and is apt to keep up until the next meal is taken. The pain is a steady ache and may be referred to the back or right mammary region, and is accompanied by a sense of fulness in the upper abdomen. The pain is also relieved somewhat by eructations of gas, vomiting, lavage and alkalies. The pain will last from a few days to a few weeks with an interval of comfort. Blood in the vomitus or stools is a late symptom and diagnosis should be made before this occurs. Gastric analysis is of very little value. Every patient with chronic duodenal ulcer should be subjected to surgical treatment. In early cases a cure may be obtained by medical treatment. No operation should be done on the gastro-intestinal tract for ulcer unless ulcer can be plainly demonstrated.

The Indications and Technic of Partial Gastrectomy

Dr. C. H. Frazier, Philadelphia: The resort to gastrojejunostomy in all cases is undesirable. This operation is suitable for ulcers of the pylorus when causing obstructive symptoms. Prepyloric ulcer and saddle-back ulcer not causing obstruction should be removed by resecting the pyloric portion of the stomach. Ulcers far distant from the pylorus, as in the fundus, should be removed by partial excision. In the development of the radical operation for carcinoma of the pyloric portion of the stomach, too little attention is paid to the topographic anatomy of the lymph nodes. Operation to be radical should include removal of the six primary lymph chains, namely, the suprapyloric, inferior coronary, right paracardial, gastro-epiploic, subpyloric or retropyloric and the suprapancreatic. The retropyloric ulcers are the most frequently overlooked and the suprapancreatic are the most difficult to remove.

Delayed vs. Immediate Operation for Extrauterine Pregnancy

Dr. C. A. Stillwagen, Pittsburg: Hemorrhage and shock in terminated ectopic pregnancy are rarely severe enough to cause death. In cases in which hemorrhage is severe and persistent, death not infrequently results before operative treatment can be instituted. Patients who survive the initial hemorrhage, but are profoundly shocked and anemic, can be more safely treated by delaying operation until the condition improves, than by immediate laparotomy. Operation should be performed as soon as possible after termination of ectopic pregnancy, provided it can be done with safety to the patient. In selecting the time, every surgeon will, of course, use his own judgment, but he must show a low mortality in order to justify any given plan of procedure.

Surgery as a Prophylactic Measure Against Intestinal Complications in Typhoid

Dr. L. J. Hammond, Philadelphia: When, during the course of typhoid, there is reasonable certainty of the existence of bands or adhesions especially affecting the functions of the intestinal tract at any of its flexures and sufficient to produce severe abdominal symptoms, exploratory laparotomy should be done with a view to removal of mechanical barriers to intestinal activity which favor ulcerative processes going to perforation.

DISCUSSION

Dr. G. L. Hays, Pittsburg: In my experience in about fifty cases of operation for complications of typhoid none have shown any preperforative signs. While it is possible, I doubt if these signs are very frequent. Of course, if we can prevent this condition by any kind of operation, I think it would be a very good thing to do, but I do not believe that we will ever be able to perform an operation which will completely eradicate these conditions.

Relative Value of the Various Methods for the Determination of Kidney Sufficiency

Dr. B. A. Thomas, Philadelphia: The most accurate and dependable test for determination of renal function is that by quantitative metabolic study, but such study is usually impossible. Any test dependent on synchronous catheterization of the two ureters has a limited field of application. The cystoscope, together with one of the anilin dye tests, notably indigo carmin, affords the most practicable means of kidney diagnosis.

Results of Gall-Stones

Dr. J. A. McGlinn, Philadelphia: In eight out of eleven cases of cancer of the bile ducts stones were present. In a series of autopsy records of gall-stone cases various related lesions were noted. While it cannot be said that all these lesions were due to gall-stones, many undoubtedly were. These lesions can be prevented only by early operation in gall-stone cases.

The Pelvic Fascia and the Operation for Cystocele

Dr. R. E. Brenneman, Pittsburg: The bladder and anterior vaginal wall are attached to the white line which gives rise to the levator ani, and by cutting these attachments, a cystocele is produced by downward pressure. These protrusions of the anterior vaginal wall, either lateral, bilateral, complete or partial, must be considered true hernias and are produced by a variety of causes. These are repaired by restoring the normal anatomy so far as possible. This is best done by the method of White of Savannah, which I have used in several cases with success.

Cecostomy vs. Appendicostomy for Colonic Irrigation

Dr. W. M. Beach, Pittsburg: The comparative safety of cecostomy is apparent. Cecostomy or appendicostomy should always be considered as an adjuvant to medical measures to be invoked in order to treat local conditions locally. It should be considered a legitimate treatment of toxemias of intestinal origin, amebic dysentery, obstinate colitis and constipation, tuberculosis and syphilis, and it is believed to be justified as an adjuvant to medical measures in anemia, intussusception and typhoid. It is of value in acute septic peritonitis, in order that ice may be applied both internally and externally.

Oration on Obstetrics: A Plea for the More Intelligent Care of the Pregnant and Lying-in Woman

Dr. H. F. Tomb, Johnstown: Let us endeavor to have every one of these patients under the guidance of a physician from the very beginning of pregnancy. Let us make an effort to obtain better nursing and by procuring the better care and nursing get rid of the midwife and her class. Let us give to our labor cases more time and care, both during labor and the puerperium, and never discharge a patient of this kind until we have made a thorough examination.

SYMPOSIUM ON GONORRHEA

Prophylaxis of Gonorrhea

Dr. M. F. Bates, U. S. N.: In the Navy general preventive measures, such as mental and physical exercises and diversions and instruction by lectures and leaflets, have been employed to the fullest extent. Prophylactic treatment after exposure has been used in the last few years with excellent results. If administered within eight hours of exposure protection is almost certain, but even after forty eight hours it is sometimes of value

Abortive Treatment of Gonorrhea

Dr Macy Brooks, Philadelphia Gonorrhea cured within two or three weeks is to be considered aborted Abortive treatment is seldom effective later than when the discharge is just becoming mucopurulent, and there is at most a slight burning on urination Injections too strong or too frequent are harmful A daily injection by the surgeon is sufficient Should abortive treatment fail, treatment can be continued as in the usual case

Treatment of Acute Gonorrhea

Dr W F Donaldson, Pittsburg When acute gonorrhea is recognized and treated more as a pathologic condition and less as a social disease, it will take its place among curable diseases and not rank among the leading disseminators of death and destruction If it be true that acute gonorrhea is curable, it is time that we cease to be alarmists and rather educate the public that the unfortunate individual with acute gonorrhea may with early intelligent and diligent treatment be cured I would urge physicians to deal with patients infected with acute gonorrhea in such a sympathetic and dignified manner that in the course of time all such sufferers will early seek medical advice and follow it until a cure has been effected

Diagnosis and Treatment of Chronic Gonorrhea

Dr T L Disque, Pittsburg For the diagnosis of chronic urethritis it is necessary to determine the character of the discharge, make a microscopic examination of the discharge, investigate the urine and make a careful local examination of the urethra itself In the treatment disinfection by lavage with potassium permanganate is carried out until the discharge is stopped, this procedure is then followed by instillations of silver nitrate If there is infiltration of the submucosa, dilatation and massage must be practiced Of internal remedies the balsams and disinfectants are of value when the urine is turbid and the diluents when there is concentration and acidity

Discussion on Gonorrhea

Dr H M Christian, Philadelphia In the early stages of gonorrhea in local treatment, I believe that there is nothing better than the use of permanganate of potassium, though I do not believe that it will ever cure a case of gonorrhea To cure a case of gonorrhea something is required that acts on the mucous membrane of the urethra like an astringent I agree with what Dr Brooks said of the abortive treatment I feel that all chronic gonorrhea is found in the prostate I am coming to leave the anterior urethra almost out of the question unless there is present in the anterior urethra a stricture or some other involvement, but I believe that in 75 or 80 per cent of chronic urethral discharge there is prostatic involvement

Dr S W Moorhead, Philadelphia I have reluctantly come to the conclusion that the microscopic examination is in itself insufficient to demonstrate whether or not gonococci are present in a discharge and that recourse should be had to cultures This necessitates a large amount of laboratory work and equipment, but it is a work which ought to be done and which I believe will have to be done in very many cases

Dr W C Bryant, Pittsburg I think we make the mistake sometimes of being over zealous in treatment There is no doubt that acute inflammation is a beneficent process and while it may not last very long there is a time in treating some cases of gonorrhea at least, when the urethra is better left alone Permanganate of potassium should never be in stronger solution than 1/5 000

Dr T L Disque, Pittsburg What Dr Christian has said in regard to the rôle of the prostate is well taken While the prostate is a marked feature in the prolongation of chronic urethritis and probably the greatest hiding place of the gonococcus, it is not the only one and we should not neglect other portions of the urethra or the genital tract.

Clinical Results Following the Use of Vaccines and Serums in Treatment of Gonorrhea and its Complications

Dr W H MacKinney, Philadelphia The bacterial vaccines have not demonstrated their value in the treatment of acute or chronic gonorrhea or its acute complications In metastatic infections, chiefly arthritis, they have given good results in a few cases but the results cannot be compared to those obtained from the serum In the treatment of metastatic gonorrhea both the serum and the vaccine are of considerable value though they are not specifics

The Question of Marriage Following Gonorrhea

Dr George A Holliday, Pittsburg Gonorrhea is the married woman's most common disease The double standard of morality must be frowned on The girls should be taught that venereal infection will ruin her health and, therefore, that she must demand a clean bill of health from her prospective husband Most of the sterility in women is due to gonorrhea and 50 per cent of infected women are sterile Men should be instructed in prophylaxis Physicians are responsible for a large percentage of innocently infected wives because they do not thoroughly treat gonorrhea and its complications in the male

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below

Boston Medical and Surgical Journal

November 3

1 Etiology of Cholecystic Gall Stones W I Clark, Worcester Mass
2 A Fallacy in Psychotherapy J E Donley, Providence R I
3 Spontaneous Dislocation of the Hip Joint Following Acute Infectious Diseases C G Cumston Boston
4 *Technic of Arthrotomy C F Painter and A P Cornwall, Boston
5 Stomach Diseases from a Medical Standpoint G A McEvoy, Boston

4 **Technic of Arthrotomy**—Among the series of thirty excisions reported by Painter and Cornwall were one case of chondroma, three of infantile paralysis and two of infectious arthritis, one of these was a polyarthritis There was one death attributable directly to the operation, that being in the case of infectious polyarthritis There were three infected joints, but no serious consequences resulted Convalescence was not even retarded by it in any case There was one other case in which there was a stitch abscess Twenty four of the excisions were for tuberculosis Two of these patients died some months after the operation, one from miliary tuberculosis and one from phthisis One patient had a partial excision, one femoral and the corresponding tibial condyle, she secured a good degree of motion in the joint and after having an osteotomy to correct her knock knee she had a very serviceable articulation Two patients already referred to had secondary excisions Only one was lost sight of before union was complete Only one did not have satisfactory position In three only of these cases were metal sutures used, in two of these they were removed, and in one there was slight necrosis about the stitch One patient still has the wire in place

A small series of erasions follow Most of these were performed for tuberculous disease The technic of getting at the interior of the joint is not in any way dissimilar from the technic used in the excision operation The operation is not, in the author's opinion to be compared in its beneficial effects with the operation of excision Whether it be accomplished by sawing through the patella and flexing the knee, or by dividing the patellar tendon and reflecting back the patella thus exposing the quadriceps pouch, the convalescence is protracted to such an extent by the union of the bone or the tendon (whichever method is employed) that there is very little likelihood of obtaining enough motion to justify the operation in such an articulation as the knee In other joints it might be used in selected cases, but seldom in the knee The difficulty is not in securing a pathologic cure, but in procuring enough function to justify the operation. One of the things that has been brought out from a study of these cases and the excisions is that tuberculosis in the knee, at any rate, starts very much more frequently than has generally been supposed from the synovial membrane, and is likely to invade the cartilage and bones if a tuberculous synovial pannus be allowed to lie too long in contact with such structures. In certain selected cases erasion and the procurement of a pathologic cure, even though very little motion should be secured, the patient might be subjected later to an arthroplasty to secure motion. Several of these patients have had 20 degrees of motion for a year or so after the operation, but have gradually lost it and have been a great deal better off when ankylosis had taken place.

28. **Sacro-Iliac Strains.**—In a greater number of the acute strains of the sacro-iliac joints, Morrill found that only one side is affected, and that by pressure one can generally tell which it is. The motions of the body are more or less guarded, depending on the severity of the case, especially those motions that bring any strain on the injured joint. Thus, in forward bending, the patient will lean slightly toward the opposite side, thus removing any strain from the injured side, and lateral bending is also restricted in the lower portion of the spine in leaning toward the well side, while toward the injured side it is included in the general curve. This is caused by the spasm of the erector spinæ muscles on the affected side. In backward bending the entire trunk is often held rigid, and it may be impossible for the patient to regain an upright position. Often in severe cases the greater part of the body weight is thrown on the sound side and one may find a marked curve in the lower spine, with perhaps a compensatory one higher up, caused by the tilting of the pelvis laterally to relieve the injured joint. In these cases the hip on the affected side is the more prominent, and the leg seems longer, the patient standing with the knee bent. With the normal individual it is possible, with the patient either seated or lying down with the knee extended, to raise the leg to a right angle; but in sacro-iliac injuries this motion is limited on the affected side. The most common causes for acute strains are said to be in rising suddenly from a stooping position while lifting a heavy object, or in suddenly putting the entire weight on one leg before the muscles holding the sacro-iliac joints have had time to contract; as in stepping into a hole or slipping when lifting anything. In these cases there may be a partial dislocation, which may or may not reduce itself. With the female this is much more apt to occur during the menstrual period, as at these times the sacro-iliac joints naturally loosen. These joints account for the sciatica that is so often noticed in pregnant women, and a great improvement usually follows the application of a properly fitting apparatus which holds the joints together and yet does not press on the abdominal wall. Most chronic cases are due to unreduced dislocations or to a bad poise of the body either natural to the individual or assumed; good examples of the latter are found in severe cases of painful flatfoot. In the acute cases an adhesive plaster strapping is applied to the back, to hold the joints together until a properly fitting belt can be made. This is done to rest the muscles and to aid them in regaining their normal strength. Later, certain exercises are necessary. If in the severe cases the treatment does not relieve the patient, the joint should be carefully manipulated; this usually requires ether, as nitrous oxid does not entirely relax the muscles. A plaster jacket is then put on, great care being taken to obtain the normal lordosis and to fit the jacket sufficiently to the pelvis so that the joint will not slip out. Sometimes nothing is accomplished at the first manipulation except the stretching of the adhesions. Often it will be found necessary to apply a light spring back brace, after the plaster jacket is removed, to assure oneself that the trouble will not return again from bad posture, and also to retain the normal lordosis until the patient learns to stand properly. There is one important thing that Morrill calls attention to, namely, that ordinarily when a patient is placed on an operating table under an anesthetic no provision is made to maintain the normal curves of the spine. When the muscles are relaxed these curves are lost, and with the legs extended or perhaps tied down, the psoas and iliacus must stretch. Now, if a small pillow is placed under the lumbar spine and a larger one beneath the knees this cannot happen. The surgeon has this advantage: if this is followed out, the abdominal muscles are lax and therefore can be retracted more easily and the pelvic organs are more nearly in their normal positions. The pelvis is, of course, slightly deeper, but the patient will not have the troublesome backache with perhaps sciatica, that so often causes suffering after an operation.

42. **Multiple Neuritis of Fowls.**—In one of Kilbourne's experiments a fowl, fed on a reduced amount of neuritis-preventing, undermilled rice, died with signs and symptoms of neuritis, and microscopic examination showed degeneration of its nerves. From the signs and symptoms exhibited, Kilbourne believes that another fowl, as a result of starvation for twenty-three days, developed multiple neuritis. This fowl was chloroformed and its nerves examined after standing in osmic acid and teasing in glycerin. Degeneration was found. Spasticity, Kilbourne says, is a late development of neuritis in fowls. He is now conducting further experiments with a larger series of birds.

43. **Tuberculosis of Infants and Children.**—According to statistics taken from the last annual report of the Bureau of Health of the Philippine Islands, the total mortality of infants, from birth to 1 year old, in Manila, caused by miscellaneous diseases was 4,090. Thirty-nine of these died of tuberculosis, distributed as follows: seventeen died of pulmonary tuberculosis; three of tuberculous peritonitis and nineteen of tuberculous meningitis. Of the 4,090, 764 died of infantile beriberi, and 199 of gastro-intestinal diseases. The total mortality of children from 1 year to 5 years old for the same fiscal year of 1910, is 1,194. Of this number, 114 died of tuberculosis in its different manifestations, and 157 of gastro-intestinal diseases. From the above figures Sison obtains the following percentage of mortality: Death from tuberculosis in infants 0 days to 1 year old is 0.95 per cent.; and for children of 1 year to 5 years old is 9.50 per cent.; in other words, the mortality from tuberculosis in children is ten times greater than it is in infants. He says that the incidence of tuberculosis in children cannot be estimated properly from the aforesaid figures, because they represent only those who died directly from the disease, and do not include those tuberculous infants who died from some intercurrent illness. The most important factors responsible for such widespread tuberculosis in children are, in Sison's opinion: 1. Relatively, there are more persons in this country affected with tuberculosis than anywhere else, as is shown by the statistics taken in the dispensary of the Philippine Medical School. Over one-third of the patients who apply for treatment in this dispensary are suffering from tuberculosis. This wide distribution of the disease is of itself an important factor in increasing the liability of our infants and children to acquire the infection. 2. The *modus vivendi* of the lower class is exceedingly favorable to the spread of the infection. 3. The general frequency of congenital debility in children born from tuberculous parents, and the well-known inherited predisposition to tuberculosis transmitted from the parents to their offspring, are factors that answer for the ease with which the disease is propagated to infants and children. 4. Many debilitating diseases such as gastritis, gastro-enteritis, ileocolitis, produced either by errors in diet or by infections, specially common here, undermine the vital resistance of infants and children previously healthy and naturally strong, and make their organism a well-fertilized soil to receive the germ of the disease. 5. The careless and obnoxious habit of many, but particularly of the ignorant class, of spitting anywhere in the house is another source of many of the infections in children.

51. **Compensatory Hyperplasia of the Intima.**—Klotz conducted an elaborate series of experiments for the purpose of determining the exact nature of compensatory hypertrophy of the intima. He agrees with Jores and others that not one but many factors may be at work leading to intimal hyperplasia. Among these factors are mentioned infection, bacterial toxins, organic poisons, inflammation and increased arterial tension. The theory of Thoma that the connective tissue developed in the intima is compensatory, Klotz does not sustain. From the evidence which he has at hand, he says that it is not possible to state that the proliferative changes in the intima are uniformly secondary to the weakening of the media. Common influences may act simultaneously on the media and the intima. Progressive medial degeneration of the peripheral arteries (Moenckeberg's sclerosis) he regards as the result of muscle fatigue coupled with nutritional disturbance.

52. **Diagnosis of Syphilis in the Military Service.**—In the majority of cases examined by Craig in the laboratory of the office of the Surgeon-General, the result of the Wassermann test was simply confirmatory of the clinical findings. There were, however, numerous suspicious cases, or cases in which symptoms were present and the patient denied a specific history, in which the test was of the greatest value, and it is in such instances, perhaps, that it may be regarded as "the court of last resort" in arriving at a conclusion regarding the nature of the condition present. Certainly if there is any value in experience and statistics, we are justified in regarding this test as the most valuable means we possess of diagnosing lues, and our experience with the Noguchi modification of the test has justified all that has been claimed for that method. Craig believes that his results have proved that by the use of the complement-fixation test in the military service it is possible to prevent the enlistment of men suffering from latent lues who would otherwise be enlisted; to control specific treatment by using it as index of the efficiency of such treatment; to clear up the diagnosis of obscure or suspicious cases; and to enable the surgeon to avoid mistakes in discharges for disability in cases suspected of this disease. Owing to the facilities with which clinical observations can be made in armies, and the control that is possible of tested individuals, Craig hopes that the Noguchi modification of the complement-fixation test will be more widely used than it has been in the military services, for which he believes it is especially adapted. So far as Craig is aware, the Medical Department of the United States Army is the first to adopt this test as a routine diagnostic procedure and to apply it in the case of applicants for enlistment.

53. **Distribution of Fat in the Liver.**—The authors have endeavored in the work on which this paper is based to obtain some information relative to the fat which appears in the liver at death, as well as its nature and distribution. Fat which can be stained and recognized as such appears in a large percentage of all cases, irrespective of age; in the 100 cases comprised in this series, ninety-eight showed a recognizable amount of it; of twenty successive cases taken from the autopsy series, all showed it. In 100 cases, fourteen times fat was present in extreme amount, a condition certainly pathologic, for in thirteen of these when mention was made of the point, the macroscopic appearance was abnormal; thirty-two times it was considerable in quantity, which condition is probably pathologic, for it is attended by an undue friability of the organ; often, too, the lobules are much less distinct than in the normal liver. In fifty-two cases the fat was slight in amount, and twice it could not be demonstrated. These fifty-four cases are open to the interpretation that the fat is merely the expression of low vitality of the cell which is in some way prevented from carrying out completely its metabolism. The authors distinguish four types of fatty deposits in the lobules of the liver: (1) fat deposits in which globules alone are present in the lobules; (2) fat deposits in which granules alone are present; (3) fat deposits in which granules and

globules are found in the same lobule; (4) fat deposits in which globules and granules are found in the same cell. They suppose that granules indicate the (protoplasmic) change commonly spoken of as fatty degeneration, and that globules of small size are excess of fat, stored up by reason of some pathologic change which may be merely temporary. Fat is oftenest central, least often in the mid-zone. A heavy deposit of fat is compatible with a competent liver. Intense fattiness, generally globular, occurs with intoxications of bacterial and chemical nature, as well as in cases in which a complex toxin is manufactured by the body cells. Granular fat occurs oftener than globular: it affects most often the central zone; globular affects most often the peripheral. "Accidental" masses of globular fat are found at times, and appear to follow no rule of position: these are comparable to lipomata, which are evidently the result of a pathologic process. The authors found no deposit of fat characteristic of uremia. The authors know of no analysis of the liver fats in the granular and globular states, respectively: it seems to have been taken for granted that the deposits were one and the same.

70. **Abdominal Diphtheria.**—The patient entered the hospital complaining of abdominal pain. When seen, he was vomiting bile-stained fluid. Examination showed both recti muscles rigid and contracting spasmodically and equally on both sides There was tenderness all over the abdomen, but slightly more localized in the epigastrium. The source of the trouble could not be localized in any definite organ. Temperature and pulse were normal, yet the patient was very much prostrated. Leukocytes numbered 14,000. The second day the temperature and pulse were slightly elevated. Prostration and biliary vomiting continued. Pain became slightly more localized in the epigastrium. A suspicion of diphtheria was aroused by the low fever and prostration resembling that of several other diphtheria patients in the hospital at the same time. Patient's throat examination was negative clinically, but Schmitter had found diphtheria organisms in the throats of several persons of normal appearance. Hence cultures were made from the throat of this man. On the third day, a twelve-hour culture showed abundant diphtheria organisms Bowels, which were very constipated, were moved with calomel and enema. The movements had the foul odor characteristic of diphtheria. Antitoxin was prescribed, 4,000 units every six hours On the fourth day the patient was improved; mind was clearer, and he had less pain. There was also decreased rigidity of the recti. By the eleventh day all symptoms had gone. Culture from throat still showed diphtheria organisms.

74 **Maxillary Sinus.**—In an examination of 100 heads in the necropsy room, Tunis found that 37 per cent. showed some evidence of pathologic changes in the maxillary antra. Of these thirty-seven cases, eleven were examples of edema; twelve were examples of chronic inflammation or empyema; one was an example of an alveolar or dental cyst, and thirteen were examples of retention cyst. With one or two exceptions, all of these cases were undiagnosed during life. The presence of a large amount of pus in ten out of twelve of these cases of empyema, Tunis thinks, may have played an active part in causing the death of the patients. In this series there was no particular disease with which inflammatory conditions of the antra were associated. The cause of death in twenty-one of these 100 cases was tuberculosis, either of the respiratory or intestinal tract. Nevertheless, there was only one example of a tuberculous condition of the antral mucous membrane. All the cases of retention cyst were associated with a mild form of chronic atrophic catarrh, while several of the cases showed under the microscope a combination of a severe chronic inflammation and retention cyst. In the author's opinion the importance of antral inflammation as a factor in causing such diseases as inflammatory rheumatism, hay fever, asthma and pneumonia is frequently overlooked.

75 **Intralaryngeal Actinomycosis.**—The patient in this case, aged 19, a shoe-stainer by occupation, at home had lived on a farm and worked among horses and cattle. His family history was entirely negative, as was also his previous personal history. He first noticed a slight hoarseness, which gradually increased until he could speak only in a whisper; it was for this symptom alone that he sought relief. There was at times a slight "stinging" in the throat, which had never been more than disagreeable. There had been a slight cough and some dyspnea on exertion. His only antecedent nose and throat symptoms had been an occasional trifling epistaxis from the right nostril. Examination of the thorax was negative; the sputum was negative and the urine showed no deviation from the normal; temperature was normal; weight was 119 pounds; general appearance was good. The nose, pharynx and tonsils were absolutely normal and the teeth were in excellent condition and well cared for. The epiglottis was slightly thickened, and to the right of the median line, on the laryngeal surface, there was a small, whitish deposit. In the region of both true cords and completely covering and concealing them, were irregular masses of dirty white tissue, more than half occluding the chink of the glottis. The same sort of tissue lined the trachea as far down as Arrowsmith could see, which was but a short distance, by reason of the encroachment on its lumen by this adventitious material. The man was given vigorous antisyphilitic treatment for a month, without improvement. After he had been under observation for about three months, several portions of the laryngeal mass were removed and examined microscopically. The diagnosis of actinomycosis was then made. The patient was put on increasing doses of potassium iodid without apparent improvement, although there soon was no evidence of actinomycosis in the sputum. There were present occasional tubercle bacilli,

streptococci and groups of staphylococci. This condition gradually became worse. Physical signs of consolidation were discoverable in the right upper lobe. There was some cough, emaciation, irregularity of temperature, anorexia and digestive derangement. At the last examination, there was an area in the vault of the pharynx which presented an appearance identical with that in the larynx—previously there had been absolutely no lesion discoverable elsewhere than within the larynx. The physical signs then present were the classical ones of early pulmonary tuberculosis.

77. **Foreign Body in Right Bronchus.**—The foreign body in this case was a piece of a large rubber ink eraser.

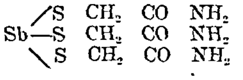
88 Immunization of Animals to the Poisons in Fungi. W. W. Ford, Baltimore.
89 *Expectorants. V. E. Henderson and A. H. Taylor, Toronto, Canada.

86. **Action of Magnesium Sulphate.**—The experiments made by Matthews and Brooks tend to confirm the curare-like action of magnesium sulphate, particularly as described by the French authors. Magnesium sulphate in doses sufficient to give marked action on the motor endings, produces little effect on the respiratory center; but in larger doses it causes depression of the center. When administered to the unanesthetized dog, primary stimulation of the respiratory movements was observed. The action of magnesium on the heart is explained as that of a depression of the cardiac nervous mechanism, involving particularly the accelerators.

87. **Experimental Trypanosomiasis.**—Incident to the search for a specific against trypanosomiasis, Abel has prepared the triamid of antimony thioglycollic acid.



This compound is obtained in the form of a thick syrup or semiresinous body, which is soluble in water in all proportions, is powerfully trypanocidal, and may be administered subcutaneously in solutions 0.010 gm. to the cubic centimeter without signs of pain or local irritation. The compound tends to deposit a little sulphid of antimony on long standing, and this is readily removed by filtration. Abel says that only solutions that have been made perfectly clear by filtration should be injected subcutaneously or intravenously. As in the case of antimonials in general, only extremely dilute solutions, that is, only such as contain one-half or at most 1 milligram in the cubic centimeter, should be injected intravenously if one wishes to avoid untoward effects. Another compound used was sodium antimony thioglycollate.  made according to the directions of Klason and Carlson and of L. Ramberg. Sodium antimony thioglycollate and the triamid of antimony thioglycollic acid were used in the treatment of white rats experimentally infected with various species of trypanosomes as *T. brucei*, *T. evansi* (both surra of India and surra of Mauritius) or *T. equiperdum*. The nagana (*T. brucei*) strain used was exceedingly virulent, killing the rats in from seventy-two to eighty-four hours regularly. The surra of India strain was practically just as virulent, while that of Mauritius and that of dourine were much less virulent. An attempt was made to protect rats against infection by administering sodium antimony thioglycollate twenty-four hours previous to the intraperitoneal inoculation with trypanosomes. No protection at all was afforded, each of the three animals so treated developing the disease in the usual time. It was found, however, that the administration of either of these drugs subcutaneously at the time of the injection of the trypanosomes was always an absolute protection against infection. The time elapsing between the date of inoculation and the beginning of treatment is the most important factor in determining the results obtained in treatment; the longer the period before the institution of treatment, the smaller the degree of success from the point of view of a radical cure; the shorter the period the greater the success. Sodium antimony thioglycollate given any time within twenty-four hours after intraperitoneal inoculation furnished an absolute protection in every instance in which it was tried. The triamid was tried similarly on two rats. One had a relapse on the twelfth day, but the other is still living after two months, and exhibits no evidence of the disease. When the treatment is deferred until forty-eight hours after the infection is given, the trypanosomes in the blood are very numerous. Administration of either drug at this time will completely remove all the trypanosomes from the blood in from one and one-half to two hours, but relapses will occur in nearly every instance unless repeated doses of the drug be administered. When a moderate dose of either preparation is given at the end of forty-eight hours and repeated on the fourth, sixth and eighth days after the infection, the blood remains free from trypanosomes for a period of two, three or four weeks, and in one instance the trypanosomes never returned.

But one experiment was made to test the efficacy of these drugs in preventing infection and that was carried out as follows: A small dose of the sodium salt was given subcutaneously at the same time with the intraperitoneal inoculation with nagana. A dose of moderate size of the same salt was given on the fifth day following and again on the tenth day. In this way the disease was entirely prevented, no trypanosomes appeared in the blood and repeated subinoculations into rats have given only negative results. Rabbits tolerate the antimonials better than the dog. These results in the way of treatment compare so favorably with those obtained by others in the use of the antimonials or arsenicals of the day in experimental trypanosomiasis that a trial of the antimony thioglycollates in human trypanosomiasis and in the trypanosomic diseases of the larger animals would seem to be justified. The authors claim that in the case of the equidæ and bovidæ these drugs may be found to be of service as prophylactic agents during periods of exposure to infection in traversing a "fly region." Their relatively low cost and their ability to induce drug resistance in trypanosomes are factors worthy of consideration in this connection. It is not claimed that these antimonials are more efficacious in the long run as therapeutic agents than those hitherto used, but that it is certainly worth while to enlarge the number of trypanocidal drugs, especially if their toxicity is less marked than that of their predecessors, or if they are better adapted for subcutaneous injection.

89. **Expectorants.**—Henderson and Taylor found that if iodids produce an increase in bronchial secretion, it must be brought about reflexly. Ammonium compounds increase secretion reflexly and possibly to a limited extent by an action on the bronchial gland center if very large doses are given. Antimony and ipecac and senega produce bronchial secretion reflexly. Emetin has a central action as well. Apomorphin stimulates the bronchial gland center. Pilocarpin stimulates the bronchial glands peripherally and atropin depresses them.

111. **Pneumococcus Polyarthritis.**—In four of the cases reported by MacCordick the patients had a previous history of acute rheumatism and one had chorea. In four the arthritis preceded other affections by an average period of about six days, and in one case the arthritis occurred three days after the onset of pneumonia. Two of these patients developed bronchopneumonia, one lobar pneumonia, and all had acute and chronic endocarditis. The two patients without pneumonia simulated closely in their course acute rheumatic fever. The organism isolated in this series of cases corresponds to the pneumococcus in every respect. The only points of special interest are low virulence for animals and unusual vitality on culture media in the case of the organisms obtained from fatal cases.

In reviewing the bacteriologic reports, it was found that only in two cases were the organisms found in blood cultures taken before death. In all it was isolated from the heart's blood after death. In the first four cases it was found in the fluid from the last affected joint. In two it was obtained from the pericardium; in one from the myocardium, and in one from the exudate over the brain and cord. From bacteriologic observations made on the cases reported and on several nonfatal cases in the wards, MacCordick says that it would appear that the disease was due to an organism of low virulence, which produces an arthritis from which it cannot easily be isolated, but that the virulence may increase so as to produce cardiac and pulmonary lesions and even death.

113. **Accidental Division of Ureter.**—This was a case of large multilocular cyst, the size of a fetal head, situated between the layers of the broad ligament on the right side. There were extensive adhesions to the pelvic brim and surrounding structures. In the attempt to free the adhesions from the pelvic brim, with round-pointed scissors, the ureter was divided completely. This was at a point 1 inch internal to its natural course. It was firmly adherent to the thick cyst wall. The ureter was dissected back for three-eighths of an inch in each direction, then tension sutures placed in the masses on either side, and drawn up, thus relieving all strain on the ureter. An end-to-end anastomosis was then done, using two interrupted sutures of fine silk on either side of the ureter, while a fine continuous suture of the same material was lightly applied around the line of division, passing through all the coats except the mucosa. The patient made an uneventful recovery, and has had absolutely no trouble referable to the pelvic or renal regions, up to one year after the operation.

125. **Uric Acid in Gout.**—This is a review of present knowledge of gout, but nothing new is offered.

126. **Electrocardiogram in Clinical Medicine.**—According to James and Williams, the string galvanometer, as an instrument of precision for original study, leaves little to be desired. The ease with which it may be adjusted to standard sensitiveness, and the rapidity with which the photographic records may be made, presents a striking contrast to the technical difficulties of many physiologic methods. Once the apparatus is properly installed, comparatively little skill is required to manipulate it, and this may be readily acquired with practice. In common with all delicate and somewhat complicated physical apparatus, it is liable to occasional derangement, a liability which can be minimized by very careful attention to the original installation. When trouble does occur, it may require a rather intimate knowledge of the principles involved to ascertain its nature and make the necessary adjustments. To those who are interested in the prosecution of original study, and who are able and willing to devote a good deal of time to such work, the authors recommend the method as well worth while. It seems probable that its most important field of usefulness, so far as clinical medicine is concerned, will be the clearing up of morbid phenomena now little understood, and that once the explanations have been given, the clinician will no longer need this complicated apparatus to enable him to recognize and understand the conditions it has explained. Just how much information regarding the effect of treatment in disease of the heart can be obtained by the use of this method cannot as yet be stated, but it seems likely that there is opportunity for fruitful work in that direction. One of the chief merits of the method is that it makes possible the study of cardiac pathology from the functional as well as anatomic standpoint. That the galvanometer may prove a great aid in the diagnosis of an occasional obscure case, experience has shown; but considered simply as an aid to diagnosis, its cost and the time requisite to secure the necessary familiarity with its manipulation will preclude its extensive use.

127. **Intestinal Amebiasis.**—Brem and Zeiler have apparently cured fourteen amebic infections with ipecac: eight with dysentery, followed from six weeks to five and one-half months

with repeated examinations for amebæ; three with dysentery, followed less than six weeks; three without dysentery, followed from two to five months. They have failed to eradicate the infection in four cases, but these patients were not thoroughly treated. The thickness of the salol coat of the ipecac pills must be carefully regulated so as to prevent vomiting on the one hand, and on the other, the passage of intact pills through the intestinal canal. Probably the best dosage and method of administration is to begin with 60 or 80 grains at bedtime and decrease the dose 5 grains daily until a dose of 10 grains is reached. Rapid cures may sometimes be effected by giving 40 grains three times during twenty-four hours. The patient should be at rest in bed and on liquid diet; no solid food or milk should be given for at least six hours previous to the ipecac, and no liquids for three hours previous. No opiate is necessary. The authors' experience indicates that a large proportion of amebic infections can be eradicated by ipecac treatment.

129. **Leg and Arm Phenomena in Tetany.**—Pool again calls attention to a case reported in 1906, in which, among the significant features of the disease, were frequent attacks of symmetrical and bilateral tonic contractures of the hands and feet and the presence of Chvostek's and Trousseau's signs, the latter being characterized by slow contractions accompanied and preceded by cramp-like pains. Contractures also resulted from making the sciatic nerve tense by holding the patient in a sitting position, so that the trunk and thighs were flexed beyond a right angle, with the legs extended; or by putting the nerves of the brachial plexus on the stretch by elevating the arm above the head with the forearm extended (extreme abduction). The contracted muscles were always board-like to the touch.

130. **Cardiorespiratory Murmurs.**—In 228 apparently normal individuals (ninety-five males, 133 females) a cardiorespiratory murmur was heard in but two instances. These patients were examined but once, in the erect posture and during normal respiration and during deep breathing. Of twenty-six general medical cases (twenty-one males, five females), cardiorespiratory murmurs were heard seven times. In four instances the murmur seemed dependent on a tachycardia; two of these patients (females) had exophthalmic goiter, while the other two (males) had a murmur, apparently due to nervous palpitation, which disappeared as the heart quieted down. In the other three the condition present was chronic gastritis, aortic regurgitation, and a convalescent pneumonia in which the left base had been involved. Of seventy-four tuberculous cases, (forty-five males, twenty-nine females), a cardiorespiratory murmur was present twenty-nine times (twenty-three males, six females). Of 143 cases, representing a variety of conditions, but for the most part cases of tuberculosis, specifically examined for a cardiorespiratory murmur, the murmur was heard in thirty-two instances. Of this number, sixteen had undoubted tuberculosis. Observations were also made on 1,552 men entering the freshmen class of Cornell University in the fall of 1909. In the examination of these cases the excitement incident to the ordinary medical case is almost negligible. After auscultation of the heart and lungs, the students were required to "chin" themselves as often as possible, and then the heart and lungs were again auscultated. In many instances murmurs were then heard which had not been noticed previously. Cardiorespiratory murmurs were heard in 181 instances (11.8 per cent.). In addition to these 181 transient cardiorespiratory murmurs, there were 117 instances of accidental murmurs, apparently endocardial in origin. In all, there were 131 cases in which a subclavian murmur was heard: males, twenty-three, females, eight; tuberculous cases, twenty; non-tuberculous cases, eleven; murmur on the right side only, eight; murmur on the left side only fourteen; murmur on both sides, nine: murmur during inspiration only, twenty-three; murmur during expiration only, six; murmur during both, two; tuberculous disease of the right apex, eight; tuberculous disease of the left apex, two; tuberculous disease of both apices, five. In two cases change of posture influenced the murmur; in one the murmur disappeared in the recumbent posture, while in the other the recumbent posture brought the murmur out. In seven cases a cardiorespiratory murmur was also present.

131. **Prognosis in Chronic Valvular Disease.**—Allyn holds that the prognosis of chronic valvular disease of the heart in private practice is much better, both as to duration and capacity for work, than most persons realize. It is no uncommon experience to find persons who have sustained these lesions for ten, fifteen and twenty years, in some cases much longer, without either great discomfort or great impairment of activity. The patients who sustain these lesions longest and with least embarrassment are those of temperate habits and spare build who do not easily become angered or worried and who are controllable as to their mode of life and activities. Those who can lead a quiet, sheltered, protected life naturally live the longest. When death occurs it is usually the result of some accident or intercurrent disease, not directly from the heart. In estimating the prognosis in a particular case, Allyn says that one needs to keep in mind the distinction between a heart lesion and heart disease. So long as there is only a lesion the prognosis is good. A lesion ceases to exist and disease sets in when the heart enlarges and subjective symptoms appear. In his opinion, subjective symptoms are better guides to the functional energy of the heart and to its lasting power than are objective signs. In angina pectoris the duration may be five years instead of the conventional one or two, just as some cases of aortic insufficiency may, under favorable conditions, last for thirty or forty years instead of ten years.

2. Intracranial Diseases with Nasal Symptoms.—Stewart relates the details of twelve cases of intracranial lesions in which the nasal, cochlear, vestibular, or laryngeal symptoms were of special diagnostic value.

Case 1.—Tumor in region of optic chiasm: There was optic atrophy in both eyes, with total blindness of the right eye and temporal hemianopia of the left—signs pathognomonic of a lesion of the optic chiasm. The pupil in the blind eye did not react to light, the other reacted sluggishly. All the other cranial nerves were normal.

Case 2.—Right sided extracerebellar tumor arising from auditory nerve: There was intense double optic neuritis. The right eye was totally blind; vision in the left was reduced to 6/12. Hearing in the right ear was slightly diminished, both to aerial and to osseous conduction. The muscles of mastication, face, palate, and tongue were normal. There was no cutaneous anesthesia or analgesia; nor was there any motor weakness of the trunk or limbs. The gait was unsteady and reeling. The cerebellar gait and posture of the head, the slight deafness of the right ear, and dysdiadokokinesia of the right hand, inclined Stewart to a diagnosis of right sided extracerebellar growth, which was confirmed at operation.

Case 3.—Bilateral extracerebellar tumors arising from auditory nerve: A glass-cutter, aged 40, noticed gradual deafness in both ears, more marked in the left ear, of about five years' duration. Twelve months ago he became frequently giddy and staggered in his walk, occasionally falling down. He had occasional occipital headache, but no nausea or vomiting and no disturbance of vision. He had optic neuritis in both eyes, more intense in the left. The pupils were equal and normal There was nystagmus on lateral deviation to either side. There was nerve deafness of both ears, more marked in the left ear. He complained of vague bilateral tinnitus There was moderate dysdiadokokinesia of the left upper limb The gait was reeling and unsteady. The posture of the head was suggestive of cerebellar disease The diagnosis made was that of left-sided extracerebellar growth.

Case 4.—Right-sided intracerebellar tumor: The patient had marked optic neuritis in both eyes. The visual fields were normal. Smell, taste, and hearing were acute on both sides There was doubtful unsteadiness of the right hand on touching the nose. The gait was reeling and unsteady, the patient lurching to the right, and the right leg was more unsteady than the left on touching the opposite knee The reeling gait and the unsteadiness of the right arm and leg pointed to a right sided cerebellar lesion, which was confirmed at operation.

Case 5 Syringomyelia with nuclear paralysis of the larynx: This was a fairly typical case of syringomyelia, in which the gliomatous process had extended into that part of the vagal nuclei which supplies the laryngeal muscles.

Case 6.—Syringomyelia with nuclear paralysis of palate, larynx, and tongue. This was evidently a case of syringomyelia in which the gliomatous process extended upward in the medulla to the nuclei of the hypoglossal and vagus, being more marked on the right side.

Case 7 Congenital unilateral intramedullary lesion of the medulla The absence of the right sternomastoid and trapezius together with the paralysis of the palate and vocal cord in the same side, led Stewart to diagnose a congenital lesion of the spinal accessory and vagal nuclei on the right side. Further, atrophy of the right half of the tongue, and absence of the depressor muscles of the hyoid bone, showed that the lesion extended downward through the hypoglossal nucleus to the anterior cornu of the upper two or three segments of the spinal cord The patient died. There was absence of the motor nuclei of the vagus, spinal accessory, and hypoglossal on the right side, together with diminution in size of the anterior cornu on the right side of the upper cervical part of the spinal cord, and atrophy of the spinal root of the trigeminal nucleus.

Case 8 – Right sided thrombosis of the medulla.

Case 9.—Left sided bulbar thrombosis: The symptoms in this case pointed clearly to a lesion in the left ponto medullary angle, apparently of the nature of a syphilitic thrombosis of the posterior inferior cerebellar artery, interrupting the path for temperature and pain from the opposite side of the body, and leaving unaffected that for tactile sense, which runs more mesially in the formatio reticularis. The lesion also implicated the part of the vagal nucleus (nucleus ambiguus) associated with the motor innervation of the palate, which cleared up, and of the vocal cord, which remained paralyzed. At the time of onset, the adjacent inferior peduncle of the cerebellum was also temporarily implicated, producing the reeling and forced movements to the left, nystagmus, and vertigo, while there appears to have been some interference with the pyramidal paths, which largely cleared up.

Case 10.—Left-sided thrombosis of medulla.

Case 11.—Right sided extramedullary lesion; caries of sphenoid bone.

Case 12.—Extramedullary gumma of right side of medulla.

5. Stroma of the Endometrium.—The following summary of his paper is made by Young:

1 The stroma of the endometrium consists of a soft semifluid protoplasmic mass imperfectly differentiated into cellular elements

2 The cells anastomose freely with each other by means of protoplasmic processes They present many and varying alterations in shape, but these are easily dispelled, and the cells then approximate to the typical stellate shape The differentiation of the stroma cells is thus probably more apparent than real

3 The intercellular spaces, in all probability, do not communicate directly with one another The anastomosing processes are not, as is usually stated, filaments, but films of protoplasm, which under ordinary circumstances close in the fluid cavities

4 The intima and media of the vessels are nothing more than ordinary flattened stroma cells This shape they easily lose

5 Except in the deepest layers of the mucosa the vessels have no specialized supporting coats (muscle, elastic tissue).

6 The vessels are obviously so constructed as to allow a ready and universal opening up of their walls, and the structure and consistence of the stroma such as to permit its ready displacement by fluid or blood

7 The edematous infiltration of the tissues which precedes the hemorrhagic escape, is due neither to a mechanical displacement or filtration of fluid from the vessels, nor to a secretory activity of the intimal cells It is dependent on protoplasmic changes, which result in an active inhibition of fluid from the vessels, by a process of osmosis So far as is at present known, this change is due to a widespread liberation of crystalloidal elements in the tissues.

8. The infiltration of the stroma with blood corpuscles is, in all probability, due to exactly the same cause. In consequence of its peculiar structure, the uterine mucosa must be looked on, throughout its entire extent, as a potential blood sponge.

In conclusion, Young states that his investigations have revealed that the peculiar structural conformation of the endometrium is intimately bound up with the changes which occur during pregnancy. The vascular gaping round the young ovum occurs in a manner identical in nature to, and differs only in degree from, the mode in which the vessels open up during menstruation.

12. **Intestinal Obstruction Due to the Uterus.**—The first case reported by Gottschalk was as follows: Four years ago the patient had undergone a laparotomy operation for right adnexal tumor, probably gonorrheal. The closed left Fallopian tube had been opened by salpingostomy in order to create a possibility for conception. The consequence was that on the left side numerous peritoneal adhesions formed, and the newly-formed ostium of the tube was again closed definitely through adhesion with the adjoining sigmoid flexure. The strong left peritoneal adhesions, easily inflamed, Gottschalk believes, allow the induction that from the artificial ostium infectious micro-organisms emigrated into the pelvic cavity in a secondary manner; the extended formation of adhesions had nothing to do directly with the laparotomy, otherwise, no doubt, they would have established themselves on the right side, where the diseased adnexa were removed, and in the neighborhood of the laparotomy wound. There was no sign of any adhesive formations. There remained a void space, because on the right side no adhesions formed; through this hole the loop of the ileum slipped into Douglas's pouch, which was surmounted by adhesions and by the retroverted and fixated uterus. The retroversion was formed in a secondary manner in connection with the operation, no doubt on account of the pelvic peritonitis of the left side. The case is of importance, not alone through the strangulation of the ileum by the retroverted uterus, but because it shows that salpingostomy is not without danger under certain circumstances—namely, that inflammatory micro-organisms may penetrate through the new ostium into the pelvic cavity. The case, therefore, serves as a warning example to be very careful with the indication for salpingostomy. It also shows how difficult it is to predict in advance whether an artificial tube ostium will remain open. In the second case reported obstruction was due to a retroverted puerperal uterus.

32 Treatment of Asiatic Cholera with an Anti-Endotoxic Serum. R. T. Hewlett.
33 Action of Chlorin on Water Containing the Cholera Vibrio. H. W. Harding.

31. **Thrombosis of the Lateral Sinus.**—The first case reported by Wood was a fairly typical case of thrombosis of the lateral sinus. The following are the main points of importance: (1) Cessation of discharge; (2) sudden onset of pain behind the ear; (3) tenderness along the internal jugular vein; (4) shivering (rigors); (5) Griesinger's symptom (tenderness and slight edema over the site of the emissary vein, although no tenderness or swelling over the mastoid antrum); (6) the disc normal; (7) consciousness unimpaired.

In the second case, a diagnosis of meningitis was made. Meningitis was present, but in addition there was a completely thrombosed sinus, a perisinus abscess and an extradural abscess. The points in favor of meningitis were: (1) continuous high fever and no rigors until after the operation; (2) the dull and drowsy condition of the patient; (3) the head retraction with pain on movement; (4) the lumbar puncture; (5) optic neuritis. During the further progress of the case several points suggested either an extradural abscess or a brain abscess. They were: the sub-normal temperature and pulse; the ocular paresis; the condition of the reflexes; headache and vomiting; hemorrhage into the left optic disc; and the variable amount of discharge from the mastoid wound. The giddiness and the nystagmus were most likely due to a localized labyrinthitis caused by an injury to the labyrinth during the first operation. The absence of rigors with a totally blocked sinus is worthy of note.

The principal points of note in the third case were: (1) the remittent temperature with free perspiration, but absence of rigors; (2) the headache and sickness; (3) the absence of optic neuritis; (4) the presence of Kernig's sign, but no symptoms of meningitis beyond this; and (5) the absence of Griesinger's symptom. In none of these cases was the internal jugular vein tied. Wood says, should rigors continue after opening the lateral sinus and the removal of clot, whether septic or not, then, and not before, is the time to ligate the vein.

34 *A Rare Case of Tumors. R. H. Castor.
35 Investigation of Pellagra. L. W. Sambon.

34. **Tumors.**—In this patient there were fibroma, "fibrifyingsarcoma" (fibrosarcoma?), neurofibroma, and a large lipoma. One tumor was an ovoidal hard mass occupying the whole of the left shoulder and more. The skin over it was moveable. It was about the size of a large cocoanut, with a distinct lobulated feel. There was slight glandular enlargement in the axilla, but there was nothing to note in the glands of the neck. It was not tender to the touch, but adherent to the parts around. The joint was freely moveable in all directions. A second ovoidal mass occupied the root of the neck on the right side. There was only partial fixation of the neck on this side, but no enlarged glands were detected. The largest tumor in the series lay just below tumor No. 1 and descended in molluscum-like folds to below the left hip of the patient. At its base it was 8 inches long, and was practically a continuation of the anterior and posterior folds of the axilla. Its widest circumference was 30 inches, and its length from the spine of the scapula to the lowest point was 15 inches. It hung like an ordinary satchel, and when grasped and lifted weighed very heavy. The tumor was almost covered with nodules, much larger than those seen in tumors Nos. 1 and 2, and the largest was almost the size of a small apple. Many of them were soft to the touch and sessile, others were distinctly pedunculated, but all were covered with skin. Large blood-vessels were seen discoursing over and around some parts of the tumor. The part of the tumor free from these nodules was that portion of it adjacent to the skin on the side of the patient where the skin was quite smooth.

Septic changes were chiefly seen in the middle folds of the tumor. It was on the whole firm and hard to the touch, but not tender. Its consistence varied, and some of the deeper portions of it were soft. A rather large, hard moveable tumor about the size of a small melon grew apparently from the under and lower portion of tumor No. 2, but was encapsuled and distinct from it. Tumor No. 5 was similar in appearance to No. 4. It was larger in size and partly obscured by No. 3 before it was removed. The skin over it was normal. It bore the usual clinical features of a fatty tumor. The four tumors first mentioned were removed, the patient making an uneventful recovery. The diagnosis was made microscopically.

2. **Intracranial Diseases with Nasal Symptoms.**—Stewart relates the details of twelve cases of intracranial lesions in which the nasal, cochlear, vestibular, or laryngeal symptoms were of special diagnostic value.

Case 1. —Tumor in region of optic chiasm: There was optic atrophy in both eyes, with total blindness of the right eye and temporal hemianopia of the left—signs pathognomonic of a lesion of the optic chiasm. The pupil in the blind eye did not react to light, the other reacted sluggishly. All the other cranial nerves were normal.

Case 2.—Right-sided extracerebellar tumor arising from auditory nerve: There was intense double optic neuritis. The right eye was totally blind; vision in the left was reduced to 6/12. Hearing in the right ear was slightly diminished, both to aerial and to osseous conduction. The muscles of mastication, face, palate, and tongue were normal. There was no cutaneous anesthesia or analgesia; nor was there any motor weakness of the trunk or limbs. The gait was unsteady and reeling. The cerebellar gait and posture of the head, the slight deafness of the right ear, and dysdiadokokinesia of the right hand, inclined Stewart to a diagnosis of right-sided extracerebellar growth, which was confirmed at operation.

Case 3.—Bilateral extracerebellar tumors arising from auditory nerve: A glass-cutter, aged 40, noticed gradual deafness in both ears, more marked in the left ear, of about five years' duration. Twelve months ago he became frequently giddy and staggered in his walk, occasionally falling down. He had occasional occipital headache, but no nausea or vomiting and no disturbance of vision. He had optic neuritis in both eyes, more intense in the left. The pupils were equal and normal. There was nystagmus on lateral deviation to either side. There was *nerve deafness of both ears*, more marked in the left ear. He complained of vague bilateral tinnitus. There was moderate dysdiadokokinesia of the left upper limb. The gait was reeling and unsteady. The posture of the head was suggestive of cerebellar disease. The diagnosis made was that of left-sided extracerebellar growth.

Case 4.—Right-sided intracerebellar tumor: The patient had marked optic neuritis in both eyes. The visual fields were normal. Smell, taste, and hearing were acute on both sides. There was doubtful unsteadiness of the right hand on touching the nose. The gait was reeling and unsteady, the patient lurching to the right, and the right leg was more unsteady than the left on touching the opposite knee. The reeling gait and the unsteadiness of the right arm and leg pointed to a right-sided cerebellar lesion, which was confirmed at operation.

Case 5.—Syringomyelia with nuclear paralysis of the larynx: This was a fairly typical case of syringomyelia, in which the gliomatous process had extended into that part of the vagal nuclei which supplies the laryngeal muscles.

Case 6.—Syringomyelia with nuclear paralysis of palate, larynx, and tongue. This was evidently a case of syringomyelia in which the gliomatous process extended upward in the medulla to the nuclei of the hyperglossal and vagus, being more marked on the right side.

Case 7.—Congenital unilateral intramedullary lesion of the medulla: The absence of the right sternomastoid and trapezius, together with the paralysis of the palate and vocal cord in the same side, led Stewart to diagnose a congenital lesion of the spinal accessory and vagal nuclei on the right side. Further, atrophy of the right half of the tongue, and absence of the depressor muscles of the hyoid bone, showed that the lesion extended downward through the hypoglossal nucleus to the anterior cornu of the upper two or three segments of the spinal cord. The patient died. There was absence of the motor nuclei of the vagus, spinal accessory, and hypoglossal on the right side, together with diminution in size of the anterior cornu on the right side of the upper cervical part of the spinal cord, and atrophy of the spinal root of the trigeminal nucleus.

Case 8.—Right-sided thrombosis of the medulla.

Case 9.—Left-sided bulbar thrombosis: The symptoms in this case pointed clearly to a lesion in the left ponto-medullary angle, apparently of the nature of a syphilitic thrombosis of the posterior inferior cerebellar artery, interrupting the path *for temperature and pain from the opposite side of the body*, and leaving unaffected that for tactile sense, which runs more mesially in the formatio reticularis. The lesion also implicated the part of the vagal nucleus (nucleus ambiguus) associated with the motor innervation of the palate, which cleared up, and of the vocal cord, which remained paralyzed. At the time of onset, the adjacent inferior peduncle of the cerebellum was also temporarily implicated, producing the reeling and forced movements to the left, nystagmus, and vertigo, while *there appears to have been some interference* with the pyramidal paths, which largely cleared up.

Case 10.—Left-sided thrombosis of medulla.

Case 11.—Right-sided extramedullary lesion; caries of sphenoid bone.

Case 12.—Extramedullary gumma of right side of medulla.

5. **Stroma of the Endometrium.**—The following summary of his paper is made by Young:

1. The stroma of the endometrium consists of a soft semifluid protoplasmic mass imperfectly differentiated into cellular elements.
2. The cells anastomose freely with each other by means of protoplasmic processes. They present many and varying alterations in shape, but these are easily dispelled, and the cells then approximate to the typical stellate shape. The differentiation of the stroma cells is thus probably more apparent than real.
3. The intercellular spaces, in all probability, do not communicate directly with one another. The anastomosing processes are not, as is usually stated, filaments, but films of protoplasm, which under ordinary circumstances close in the fluid cavities.
4. The intima and media of the vessels are nothing more than ordinary *flattened stroma cells. This shape they easily lose.*
5. Except in the deepest layers of the mucosa the vessels have no specialized supporting coats (muscle, elastic tissue).
6. The vessels are obviously so constructed as to allow a ready and universal opening up of their walls, and the structure and consistence of the stroma such as to permit its ready displacement by fluid or blood.
7. The edematous infiltration of the tissues which precedes the hemorrhagic escape, is due neither to a mechanical displacement or filtration of fluid from the vessels, nor to a secretory activity of the intimal cells. It is dependent on protoplasmic changes, which result in an active inhibition of fluid from the vessels, by a process of osmosis. So far as is at present known, this change is due to a widespread liberation of crystalloidal elements in the tissues.

8 The infiltration of the stroma with blood corpuscles is in all probability, due to exactly the same cause In consequence of its peculiar structure, the uterine mucosa must be looked on, throughout its entire extent, as a potential blood sponge

In conclusion, Young states that his investigations have revealed that the peculiar structural conformation of the endometrium is intimately bound up with the changes which occur during pregnancy. The vascular gaping round the young ovum occurs in a manner identical in nature to, and differs only in degree from, the mode in which the vessels open up during menstruation.

12. **Intestinal Obstruction Due to the Uterus**—The first case reported by Gottschalk was as follows Four years ago the patient had undergone a laparotomy operation for right adnexal tumor, probably gonorrheal The closed left Fallopian tube had been opened by salpingostomy in order to create a possibility for conception The consequence was that on the left side numerous peritoneal adhesions formed, and the newly formed ostium of the tube was again closed definitely through adhesion with the adjoining sigmoid flexure The strong left peritoneal adhesions, easily inflamed, Gottschalk believes, allow the induction that from the artificial ostium *infectious micro organisms emigrated into the pelvic cavity* in a secondary manner; the extended formation of adhesions had nothing to do directly with the laparotomy, otherwise, no doubt, they would have established themselves on the right side, where the diseased adnexa were removed, and in the neighborhood of the laparotomy wound There was no sign of any adhesive formations There remained a void space, because on the right side no adhesions formed; through this hole the loop of the ileum slipped into Douglas's pouch, which was surmounted by adhesions and by the retroverted and fixated uterus The retroversion was formed in a secondary manner in connection with the operation, no doubt on account of the pelvic peritonitis of the left side The case is of importance, not alone through the strangulation of the ileum by the retroverted uterus, but because it shows that salpingostomy is not without danger under certain circumstances—namely, that inflammatory micro organisms may penetrate through the new ostium into the pelvic cavity The case, therefore, serves as a warning example to be very careful with the indication for salpingostomy. It also shows how difficult it is to predict in advance whether an artificial tube ostium will remain open. In the second case reported obstruction was due to a retroverted puerperal uterus

31 *Three Cases of Thrombosis of the Lateral Sinus T W Wood
32 Treatment of Asiatic Cholera with an Anti Endotoxic Serum R T Hewlett
33 Action of Chlorin on Water Containing the Cholera Vibrio H W Harding

31 **Thrombosis of the Lateral Sinus**—The first case reported by Wood was a fairly typical case of thrombosis of the lateral sinus The following are the main points of importance· (1) Cessation of discharge, (2) sudden onset of pain behind the ear; (3) tenderness along the internal jugular vein; (4) shivering (rigors); (5) Griesinger's symptom (tenderness and slight edema over the site of the emissary vein, although no tenderness or swelling over the mastoid antrum), (6) the disc normal, (7) consciousness unimpaired

In the second case, a diagnosis of meningitis was made Meningitis was present, but in addition there was a completely thrombosed sinus, a perisinus abscess and an extra dural abscess The points in favor of meningitis were· (1) continuous high fever and no rigors until after the operation, (2) the dull and drowsy condition of the patient, (3) the head retraction with pain on movement, (4) the lumbar puncture, (5) optic neuritis. During the further progress of the case several points suggested either an extradural abscess or a brain abscess. They were. the sub normal temperature and pulse, the ocular paresis; the condition of the reflexes, headache and vomiting; hemorrhage into the left optic disc, and the variable amount of discharge from the mastoid wound The giddiness and the nystagmus were most likely due to a localized labyrinthitis caused by an injury to the labyrinth during the first operation. The absence of rigors with a totally blocked sinus is worthy of note

The principal points of note in the third case were: (1) the remittent temperature with free perspiration, but absence of rigors, (2) the headache and sickness, (3) the absence of optic neuritis, (4) the presence of Kernig's sign, but no symptoms of meningitis beyond this, and (5) the absence of Griesinger's symptom In none of these cases was the internal jugular vein tied Wood says, should rigors continue after opening the lateral sinus and the removal of clot, whether septic or not, then, and not before, is the time to ligate the vein

34 *A Rare Case of Tumors R H Castor
35 Investigation of Pellagra L W Sambon

34 **Tumors**—In this patient there were fibroma, "fibrifyingsarcoma" (fibrosarcoma?), neurofibroma, and a large lipoma One tumor was an ovoidal hard mass occupying the whole of the left shoulder and more The skin over it was moveable It was about the size of a large cocoanut, with a distinct lobulated feel There was slight glandular enlargement in the axilla, but there was nothing to note in the glands of the neck It was not tender to the touch, but adherent to the parts around The joint was freely moveable in all directions A second ovoidal mass occupied the root of the neck on the right side There was only partial fixation of the neck on this side, but no enlarged glands were detected. The largest tumor in the series lay just below tumor No 1 and descended in molluscum like folds to below the left hip of the patient At its base it was 8 inches long, and was practically a continuation of the anterior and posterior folds of the axilla Its widest circumference was 30 inches, and its length from the spine of the scapula to the lowest point was 15 inches It hung like an ordinary satchel, and when grasped and lifted weighed very heavy The tumor was almost covered with nodules, much larger than those seen in tumors Nos 1 and 2, and the largest was almost the size of a small apple Many of them were soft to the touch and sessile, others were distinctly pedunculated, but all were covered with skin Large blood vessels were seen discoursing over and around some parts of the tumor The part of the tumor free from these nodules was that portion of it adjacent to the skin on the side of the patient where the skin was quite smooth

Septic changes were chiefly seen in the middle folds of the tumor It was on the whole firm and hard to the touch but not tender Its consistence varied and some of the deeper portions of it were soft A rather large, hard moveable tumor about the size of a small melon grew apparently from the under and lower portion of tumor No 2 but was encapsuled and distinct from it Tumor No. 5 was similar in appearance to No 4 It was larger in size and partly obscured by No 3 before it was removed. The skin over it was normal. It bore the usual clinical features of a fatty tumor The four tumors first mentioned were removed, the patient making an uneventful recovery The diagnosis was made microscopically

38 *Hemeotoxic Nature of Eclampsia H J Murray
39 *Cysts of the Ovaries and Fallopian Tubes A Keith and A. Doran
40 Annual Variation of the Birth Rate in the Government Maternity Hospital, Madras G G Giffard and H. Ll Jones

38 **Nature of Eclampsia.**—Experiments which he carried out, in Murray's opinion, seemed to prove conclusively that it was the autolytic rather than the purely placental element which produced the anaphylaxis. Liver was substituted for placenta. Three guinea-pigs received intraperitoneally 0.5 c.c., 1 c.c. and 2 c.c. respectively of a fresh emulsion of one-half of a guinea-pig's liver, in 40 c.c. saline and three weeks later 10 c.c. of a fresh emulsion of guinea-pig's liver in 25 c.c. saline, without obvious result. On the other hand, two pigs receiving, at the same interval of time, the same amounts of liver which had been allowed to autolyze in an incubator for twenty-four hours at 37 C. showed undoubted anaphylaxis, consisting of cough, nasal irritability, respiratory embarrassment, paralysis of the hind legs, and, in one case, of slight clonic convulsions. A control showed that the amount of autolyzed liver given was not directly toxic in a single dose. Two guinea-pigs were given intraperitoneally 3 c.c. and 4 c.c. respectively of the serum taken post-mortem from the heart of a fatal case of eclampsia. Two days later each received 10 c.c. of normal amniotic fluid, without result. A third guinea-pig, which received as a first dose 4 c.c. of the fluid from the peritoneal cavity and the above dose of amniotic fluid, remained quite unaffected. There is, then, says Murray, but little satisfactory evidence that eclampsia is anaphylactic in nature. Clinically, too, the picture of anaphylaxis does not greatly resemble it, and, convulsions apart, they have little in common. A guinea-pig with the paralytic train of symptoms most marked is alive to external stimuli, and will endeavor to crawl toward its cage while any motor power remains—a marked contrast to the dazed mental state of eclamptics. The pre-eclamptic state, also, has no counterpart in the anaphylactic condition; and, finally, undoubted anaphylaxis, as seen in the human subject, is very dissimilar to the laboratory picture.

39 **Cysts of Appendages.**—After careful study of specimens and consideration of the anatomy and embryology of all structures concerned, Keith and Doran classify broad ligament cysts as follows:

1. The cyst of the lower end of the ovarian fimbria, originating in a homologue of the rete testis in the male, some tubular or cystic relic in the hilum tissue of the ovary which extends into this part of the ovarian fimbria. From this cyst arises the common cystic tumor of the broad ligament, the "parovarian cyst" of gynecologists and surgeons.

2 The cyst of the Wolffian body, developed from one of its vertical tubes. This is, therefore, truly parovarian. No authentic instance of a cyst of this type becoming a large tumor has ever been reported.

3 The cyst of an accessory tubal ostium, the "accessory hydrosalpinx" of Handley.

4 Lastly, the "hydatid of Morgagni," and the similar pyriform pedunculated cyst running outward from the horizontal tube of the parovarium. The authors hold that these are neither Müllerian nor Wolffian, but are relics of the pronephros. To the same origin Kobelt's tubes may probably be traced.

October 11, No 31, pp 175-196

48 *Sea Air and Sunshine in Treatment of Tuberculosis in Children. Revillet and Debove.

43. **Detection of Simulated Deafness.**—Weiss calls attention to the discovery by Lombard of the fact that a totally deaf person does not raise his voice in speaking when a loud noise is made close to his ear, while a person with normal hearing does this unconsciously. He uses an electric apparatus which makes a loud noise close to the ear; with normal hearing the person being examined cannot help speaking louder, while the noise is in progress, and this is rendered evident by suddenly shutting off the current, stopping the noise.

45. **Scoliosis the Result of Inflammatory Tuberculosis.**—Poncet believes that infection of any kind has a tendency to invite abnormal curvature by its softening action on the bones, the weakening of the supports and its enfeebling action in general. It is thus the essential cause of scoliosis, and infection with tuberculosis is generally the one responsible. Monod in examining fifty-one children with scoliosis, found unmistakable signs of tuberculosis in 20 per cent.; others had tuberculosis in the family and in others the tuberculin tests gave positive findings, although there was nothing except the scoliosis to suggest tuberculosis. The same softening of bone tissue from an inflammatory tuberculous process is evidently responsible, Poncet says, for many cases of deformity of the bones in the young, such as painful flat-foot, genu valgum, incurved radius, coxa vara, etc., which have hitherto been classed as "tardy rachitis."

46. **Remote Results of Gastrectomy.**—Boeckel reports the ultimate outcome in seventy-six cases of cancer of the stomach during the last ten years. In twenty-one cases the growth was inoperable, and only in eleven cases was a radical operation undertaken. Of these eleven patients seven were completely cured by this means; in the four other cases the operation was attempted merely as a last resort without much hope of permanent success. In the cured patients nine-tenths of the stomach had been removed; the age of the patients ranged from 38 to 75. Direct anastomosis between the stomach and duodenum was possible in all but one of these cases. Two of this group of seven cured patients have succumbed since to an intercurrent affection. The others are in good health to date, the interval being over five years in one case.

47 **Jonnesco's Method of Anesthesia.**—Jonnesco's method of "general spinal anesthesia" has been fully described in these columns. He here replies to the criticisms it has received in Europe and America, and reiterates his declaration that his technic or its equivalent is destined to be the method of anesthesia of the future, its simplicity, benignity and general superiority over inhalation anesthesia being now established, he says, beyond question. He has applied the method in 1,005 cases, and it has been used by others in an additional 1,958. The age of the 2,963 patients ranged from 1 month to 82 years; 433 of the operations were on or above the thorax. He has not had a fatality, but two have been reported by other operators who used doses much larger than he recommends. Transient arrest of respiration occurred seven times in his experience, but five cases were in the early tentative period. The minor by-effects are growing less frequent and milder as the technic is being perfected. He replies in detail to Moorhead's criticism of the method in The Journal, Jan. 22, 1910, page 281, stating that none of the anticipated dangers has been realized in his experience.

48 **Sea Air and Sunshine in Treatment of Tuberculosis in Children.**—This report states that over 52 per cent. were cured of the 888 children with scrofulo-tuberculosis treated at a sanatorium near Cannes on the shore of the Mediterranean. The mildness of the climate and the constant sunshine are important factors in these results. Marked improvement was evident in the other children, so that positive results were obtained in over 93 per cent.

50 *Tuberculous Nephritis with Tendency to Edema. (La néphrite hydropigène tuberculeuse.) L Bernard.

October 19, No 84, pp 777-784

51 Radiotherapy in Acute Adenitis. F Jaugeas.

49. **Transscrotal Orchidopexy for Children.**—Ombredanne asserts that orchidopexy is indicated in every case in which the testicle can be felt in the inguinal region, but cannot be easily pushed down to the bottom of the scrotum, when the child is old enough to keep itself clean. He describes with seventeen illustrations his method of operating, which he says

is simple, practical, logical and rapidly executed; he has successfully applied it in twenty one cases of unilateral and in four of bilateral undescended testicle.

50. **Tuberculous Nephritis with Edema.**—Bernard regards the form of tuberculous inflammation of the kidney inducing dropsy as practically incurable, but improvement may be realized by general treatment for the tuberculosis. As the kidney permeability is not impaired and there is no uremic intoxication, there is no need for a milk diet or its equivalent. On the contrary, the patient's diet should be the strengthening and meat diet of the tuberculous, except that the dropsy has to be combated by restriction of salt, and eggs are better avoided. Energetic revulsion by repeated cupping should be applied to the kidney region with measures to promote diuresis in general. The onset of the affection is generally insidious; the patient first notices on waking in the morning that his eyelids or hands are a little swollen, but this soon subsides to recur again occasionally and finally to become permanent, and there may be hydrothorax or other accumulation of fluid in some serous cavity. The urine may be abundant or scanty, but it always contains considerable albumin with some tube casts and a few leukocytes and red corpuscles. The association of hematuria and dropsy suggests a tuberculous kidney affection, which is confirmed by the absence of symptoms on the part of the cardiovascular system and the increasing emaciation and anemia. The kidney affection may be primary or secondary, and it may prove fatal in from five to eight months, or may pass into a long chronic phase, especially in children; but the kidneys retain their permeability generally to the end, and the arterial tension persists low.

Revue de Chirurgie, Paris

October, XXX, No. 10, pp. 729-944

52 *Treatment of Arteriovenous Aneurysm. C. Monod and J. Vanverts.
53 *Operative Treatment of Compression of the Spinal Cord in Multiple Neurofibromatosis. (Intervention opératoire dans un cas de compression de la moelle cervicale au cours de la "maladie de Recklinghausen.") P. Guibal.
54 *Minor Traumatisms of the Skull. (Petits traumatismes du crane.) L. Imbert and G. Dugas.
55 Tearing Out of the Mesentery with Strangulated Hernia. J. Rabère and M. Charbonnel.

52. **Arteriovenous Aneurysms.**—Monod and Vanverts have compiled 161 cases that have been published in the literature since 1889, and summarize the details of the different groups according to the arteries involved. This was the femoral in eighty and the popliteal in thirty five cases. The general impression left by the survey is that much better results are obtainable, as a rule, from operating directly on the sac than from ligatures. The main drawback to a complete cure is the frequent coexistence of nervous lesions complicating the aneurysm and generally solely responsible for the postoperative disturbances. Only when direct action on the sac is impossible, they assert, should ligatures be given the preference. Removal of the sac offers the same advantages over incision for the arteriovenous as for the arterial aneurysms. The eleven cases of arteriovenous aneurysm of the common carotid show that ligature alone is not so ineffectual nor so dangerous as might be believed. All of the three patients treated by a four fold ligature were cured, as also in the four cases in which the sac was incised or removed.

53. **Operative Relief of Compression of the Spinal Cord in Multiple Neurofibromatosis.**—In Guibal's case symptoms developed in a woman of 40 with two grown children, suggesting compression of the spinal cord by a tumor, such as were observed in the arm, thigh, neck and elsewhere—typical neurofibromas. The total paraplegia and intense pains justified an attempt to remove the spinal tumor, although the nature of the affection warned that recurrence was more than likely. The tumor was readily exposed at the seventh cervical and first dorsal vertebræ and it shelled out with ease. The patient succumbed six days later, however, with symptoms indicating that an accumulation of blood and serum at the site of the tumor was injuring still further the flattened spinal cord, the effects being like those of total transverse section of the cord. If the operation had been done when first advised, a year or so before, the results might have been better. The woman's husband had been infected with syphilis ten years before, but the woman showed no traces of this infection.

54. **Minor Traumatisms of the Skull.**—Imbert and Dugas discuss the accidents affecting the skull which do not seem of much importance at first, but entail serious consequences later, as, for instance, in a case they report in which a child was struck on the head with a ruler, this slight injury finally entailing idiocy. The idea of operative interference seems almost absurd for these slight injuries, but the physician should not be misled, they declare, by the apparent insignificance of the symptoms which may mask serious anatomic lesions. Imbert and Dugas do not advise trephining at once in every case of traumatism affecting the skull, but they do urge careful search for minor signs revealing the seriousness of the injury, such as changes in the cerebrospinal fluid and arterial tension, lowering of the temperature, venous congestion in the face, headache, vertigo, disturbances in pulse or respiration, or both, buzzing in the ears, drowsiness and changes in the fundus of the eye and in the ear. An apparently slight injury may be followed by a hematoma, which may do serious harm unless promptly evacuated, or the slight injury may become complicated with infection or mental disturbances later. Unless there is fracture they do not advise operative interference unless functional localization of the injury is possible. The seat of the fracture may be indicated by a hematoma or blood in the ear or vicinity, but when this is lacking an exploratory incision of the skin may reveal the seat of the trouble. If the bone is intact this does no harm, while if the bone shows signs of injury the proper point for trephining is thus located.

Semaine Médicale, Paris

October 19, XXX, No. 42, pp. 493-504

56 *Practical Results of Percussion Palpation in Examination of the Heart. (Des résultats pratiques de l'examen du cœur d'après la méthode d'Orsi Grocco.) C. Frugoni.

56. **Percussion-Palpation of the Heart.**—Frugoni states that the method of touch palpation for determining the outlines of the heart has been in use in Italy for thirty years, Orsi and Grocco having introduced and perfected the technic. He extols its extreme simplicity and the value of the information thus derived. It aims to determine the oblique and the transverse diameters of the heart. The finger applied to the chest should be pressed down firmly to reduce the vibrations of the wall. The lower end of the oblique diameter, the apex, is located by inspection, palpation and light, radiating percussion, while the upper end is determined by *moderately strong percussion* along the left margin of the sternum, it is generally just above the third costal cartilage, the total diameter averaging from 8.5 to 9 cm. in adults. This oblique diameter determines the size and direction of the left ventricle, showing any displacement or enlargement. The transverse diameter is determined by palpation starting at the fourth rib or interspace, at the junction of the left third and right two thirds of the sternum, the line being carried to 1 cm. from the mammillary line. This diameter averages 7.5 or 8 cm. in the adult. The location of the right end of the transverse diameter is a faithful barometer, he says, of the contractile power of the right ventricle, and is thus extremely important for the prognosis in acute pulmonary disease and in all cases in which there is reason to fear degeneration or enfeeblement of the myocardium. When exophthalmic goiter is suspected, Grocco determines the transverse diameter on the patient at rest but standing, and then has him take some vigorous exercise, such as running, climbing the stairs, etc. The transverse diameter is then determined anew, and if a displacement of 1, 2 or 3 cm. toward the right is discovered, it is evident that there is acute dilatation of the right ventricle, as can be verified by the Roentgen rays. This readiness of the right heart to dilate after an effort is an early and almost constant symptom of exophthalmic goiter, he states, and the intensity of the phenomenon throws light also on the prognosis of the disease. Tachycardia is an entirely independent phenomenon, due to nervous influences, while the ready dilatability of the heart is a sign of muscular weakness. Another sign revealed by the percussion palpation is a band of dulness along the third left costal

cartilage in case of dilatation or hypertrophy or both of the left auricle, revealing a mitral lesion, especially mitral stenosis. Normally this horizontal band of dulness is about 1 cm. wide; the increase in width with enlargement of the left auricle has great diagnostic value in the course of acute pulmonary affections and symptomless valvular disease. Another sign brought out by percussion palpation is what he calls the pericardium hood (*capuchon péricardique*). An area of dulness fits over the base of the heart like a hood, and the clinical and post-mortem findings show that this is the sign of a special form of pericarditis at the base, with hyperplasia, in connection with the large vessels and the reflection to the aorta of the serous pericardium. This area of dulness thus fitting over the base of the heart indicates a fixed morbid process in the pericardium. When it appears in acute articular rheumatism it indicates that the heart is particularly vulnerable. It has also been found in some cases of chorea and in puerperal infection and in other diseases liable to be accompanied by the ordinary forms of pericarditis. The discovery of this area of dulness has sometimes explained otherwise mysterious fever or dyspnea. The bruits are of greater diagnostic importance than the palpation findings with disease of the aorta, he continues, and explains the reasons in detail.

68. **Treatment of Low Stenosis of the Rectum without Resection.**—Fedorow avoids the usual circular resection of a low cicatricial stricture in the rectum by drawing down the colon to form a new anus. He first mobilizes the pelvic colon through an opening in the sacrum. His technic is illustrated as he worked it out on the cadaver. It is simple and takes comparatively little time, and is a much less serious operation, he thinks, than resection of the rectum.

85. **Profuse Intraperitoneal Hemorrhages with Uterine Myomas.**—Brunner has been able to find only twelve other cases on record of this occurrence besides the one he reports, but he insists on the necessity for bearing this possibility in mind as prompt operative aid is the only means of relief. It is possible that this may sometimes have been responsible for fatalities ascribed to other causes. The symptoms are the same as with any sudden hemorrhage into the peritoneum; the knowledge of the existence of a fibroma should draw attention to this possible source for the hemorrhage; it is generally ascribed to tubal pregnancy or gastric ulcer. The correct diagnosis was made only in Brunner's case and in this not until nearly an hour had elapsed after the onset of the hemorrhage although the existence of a large fibroid tumor had long been known, the patient, aged 42, being a nurse in the hospital. Two and a half liters of fluid blood were removed from the abdominal cavity; the surface of the fibroid was a network of veins.

87. **Alcoholic Neuritis in Children.**—Eichhorst reports that he has encountered sixty-seven cases of alcohol neuritis at Zurich since 1884, all in patients over 20 except one boy of 8 who had complained for two years of pains in the lumbar region and increasing weakness in the muscles of the legs and back. The child was demonstrated before a class as an example of progressive pseudohypertrophy of the muscles with little hope of recovery, but the discovery that the boy stole out of his bed at night to drink the alcohol in the lamps, etc., cleared up the diagnosis, and under baths, massage and potassium iodid he was restored to health in a few months and he has since developed normally. The knee-jerk remained lively and there were no spontaneous pains or tenderness or paresthesias. The accumulation of fat in the paralyzed muscles was particularly evident in the calves and parts of the skin. The legs and lumbar muscles were the ones mainly affected, although there was some fibrillary twitching in the muscles of the arms. His father was a hard drinker.

88. **Causal Treatment of Eye Disease.**—Haab comments on the fact that the eye is practically part of the skin and thus shares the tendency of the skin to certain diseases, such as herpes, eczema, acne, variola and pemphigus, all of which may develop in the eye while other diseases may send their toxins to the eye. The more constitutional the origin of the morbid process in the eye the greater the tendency to involvement of both eyes. The Wassermann reaction and the newer tuberculin tests have rendered great service in differentiating the true cause in certain cases of eye disease and preventing mistaken treatment; potassium iodid, for example, he says, may do great harm by its weakening effect when an eye process is of tuberculous origin although its aspect may be more that of a syphilitic lesion, and specific treatment is contraindicated and tuberculin and general measures required when the trouble is tuberculous. With scrofulous eye affections systematic institutional treatment is indispensable, he affirms.

89 **The Tasks Now Before the Organized Profession.**—This issue of the *Correspondenz-Blatt* is a *Festnummer* on the occasion of the centennial of the medical society of the Zurich province, and Haberlin reviews the "collective tasks" now before the society. The trend of the times is toward organization, and this is especially incumbent on the medical profession in Europe on account of the extensive introduction of compulsory insurance of wage earners against sickness. In the past it has been sufficient for physicians to refrain from injuring their colleagues in any way, but this negative ethical platform is no longer broad enough, positive concerted action to protect one and all against exploitation by outsiders has now become a necessity. Conditions within the profession are also altering so that it is no longer wise to ignore the small proportion of members of the profession who cast discredit on it by their unethical conduct, the profession must take more active measures against such men in the interests of the profession itself. Responsibility to the profession is constantly growing and developing and likewise responsibility in numerous control services, in pioneer work in many lines and fields for unremunerative, self sacrificing services in various honorary positions. The development of wage earners' insurance relieves the physicians of much of their unpaid work among the poor, thus giving them time for taking a leading part in the new and wide fields of effort in various lines.

90 **Hyperemia in General Practice.**—Michalski emphasizes the value of suction and constriction hyperemia in treatment of many affections in every day practice, and he extols the simplicity and harmlessness of the technic. The cupping bells are the easiest to apply of the two methods, and five minutes' suction treatment daily may have a remarkable curative action. He has a water jet vacuum pump for regulating the suction but the rubber bulb is almost as effectual. Boils and carbuncles are the most grateful field for this method of treatment. When seen early, before they are "ripe," the suction glass alone will sometimes cure them completely in two or three days. Later, it is preceded by a small incision under ethyl chlorid, the contents are sucked out by the cupping bell without pain and healing proceeds much more rapidly than by other technics. The suction hyperemia is also effectual in mastitis, and for pains in the scar after a laparotomy, but he warns against allowing the patient to use the cupping bell without supervision. The hyperemia induced by the elastic constricting band is particularly useful, he declares, for acute joint affections, especially gonorrheal, and for felons, after an incision to permit aspiration of pus. In surgical tuberculosis the constriction should be a little tighter than with other affections and great perseverance is needed, Bier regards nine months as the average length for the course of treatment, but it may cure without mutilating operations being necessary and this is worth striving for. Cold abscesses must be sought for and the contents aspirated early. The curette is rendered superfluous, he states, by hyperemic treatment either by suction or constriction, but heart disease, diabetes and arteriosclerosis are generally accepted as contraindications for it.

94 **Allowing Parturients to Get Up Early.**—Wyder takes the practical ground that it is wisest to keep patients in bed for a time after childbirth as otherwise the laity will get the impression that women do not need to be treated as invalids after delivery. Household tasks will be resumed and the women will fail to get the needed rest and freedom from ordinary work and cares. Institutions should strive to keep the women as long as possible from their ordinary work, and this, he asserts, is the essential point, not the question as to whether they should be allowed to get up a day or so earlier.

95 **Industrial Poisonings.**—Since 1898 Zangger has been studying industrial poisoning in various industries in different countries, especially the nature of the chemicals used in certain industrial processes, and he here reviews his clinical experience at Zurich last year. The neurologic symptoms are often the first that attract the patient's attention and the true diagnosis is often rendered difficult by the similarity between the effects of certain chronic intoxications and infectious diseases, and by the great variability in the reaction of different individuals to the same poison, and by the difficulty in discovering the poison involved as it is frequently used in the industry under a fancy name or only for a certain brief period. Lead he has found used in 150 different industries, and many girls work with it without knowing that they have anything to do with lead, as in making or packing stiffened tissues, laces, fringes, bottle stoppers, paints for china, papers, varnishes, cements, and repairs for parts of electric apparatus. Carbon monoxid poisoning from portable steam engines occurred in several workers in tunnels, and in others from salamanders used in drying new plaster. The escape of water gas into a factory room caused severe headache and vomiting with speedy recovery in some of the workmen but in others weakness in the legs developed, with total amnesia, the syndrome not subsiding for weeks. He has encountered forty-five cases of severe carbon monoxid poisoning in which the patients survived, the majority presented tardy symptoms. Anilin and nitrobenzol he found used in the manufacture of washing powders, hair oil, shoe blacking and various essential oils. These substances are particularly dangerous here as they are used under fancy and various names, as perfumes and essences, so that no one suspects their poisonous nature. In two cases death was directly traceable to the nitrobenzol used in making a washing powder or shoe blacking, and in a third case a child had bloody urine the day after some shoe dressing had been applied to the bare feet. The less saturated the substance the greater the tendency to chronic disturbances, both local and general, benzin, for instance, has a lesser toxic action than benzol and the toxic action increases in allyl alcohol, acrolein, etc. This explains why the acute intoxications often display peculiar features, due more to the special physical properties of the chemical, the chronic intoxications are more the result of the chemical properties than of the physical. The majority of industrial poisonous substances, he remarks in conclusion, are fatal only with relatively large doses but they induce special and often typical syndromes, particularly on the part of the nervous system, when the system is long subjected to their influence.

104 *Muscular Rigidity as Sign of Tuberculous Apical Disease. F. M. Pottenger.

96 **Ehrlich's "606" in Syphilis.**—The substance of this symposium was given in THE JOURNAL, November 5, page 1656.

102 **Transient Blindness.**—Pollnow reports a case of transient blindness after vaccination, evidently the result of a special neuroretinitis, vision gradually becoming restored in the course of a few months. In two other cases the transient amaurosis followed scarlet fever. In all the cases the eye affection did not develop until several weeks after the apparently causal affection, and it was transient in all. In the scarlet fever patients, two brothers, the fundus showed merely retrobulbar neuritis, while in the vaccination case there was choked disc in both eyes.

104 **Rigidity of the Chest Muscles as Early Sign of Tuberculous Apical Disease.**—The experiences in America and Europe seem to have confirmed the importance of Pottenger's sign of rigidity of the muscles of the chest as an early indication of disease in the apex. He here replies to some criticisms and theorizes to explain the mechanism of the sign. It is liable to be encountered, he says, with any incipient inflammatory affection of the lung or pleura, becoming apparent at the slightest inflammatory reaction within.

117 *Case of Symmetrical Neurotic Gangrene After Spinal Anesthesia. P. Sudeck.

111. **Cosmetic Operations for Tuberculous Glands in the Neck.**—Krüger comments on the disfigurements frequently resulting from removal of enlarged glands in the neck, and then describes a non-disfiguring technic which he has successfully applied in forty cases. The incision is nearly hidden by the hair or collar, while it permits ample access to the diseased tissue. It starts at the edge of the hair on the level with and close to the mastoid process, follows the edge of the hair nearly to the back, then runs vertically down to the anterior margin of the trapezius muscle and curves with this to the clavicle and runs along above this to the sternocleidomastoid or beyond. Only a slight stretch of the vertical portion is visible, while the large flap that can thus be turned back exposes the glands fully to view.

117. **Symmetrical Gangrene After Spinal Anesthesia.**—Sudeck states that a woman of 62 developed symmetrical gangrene in the dorsum of the feet and part of the toes. The anesthesia had been applied for an operation for incarcerated hernia, and the redness and blistering were observed the morning after the operation. Goldman has reported a somewhat similar case in which the symmetrical gangrene affected the heels.

125 *Potassium Permanganate or Urochromogen Urine Test and Its Relation to the Diazo Reaction. (Neue Harnreaktion.) M. Weiss.

120. **Symptom of Acute Otitis Media.**—Blum reports that further experiences with 200 cases have confirmed his statements in regard to the early diagnosis of otitis media in children by local pressure. The Journal described the sign as follows, Nov. 30, 1907, page 1874: On placing the finger behind the angle of the jaw in the groove formed by the inferior maxillary bone and the anterior border of the sternomastoid of the affected side, and pressing upward and inward toward the auditory canal, decided evidence of pain is elicited. He says this symptom is constant in otitis media, and is of special diagnostic value in infants.

123. **Ehrlich's "606" in Syphilis.**—Meirowsky states that the "606" does not seem to have any irritating action on the kidneys. He observed rapidly transient albuminuria in only one of his eighty cases but in not less than six cases necrosis developed at the point of injection, painless for weeks until is opened outward; there was no suppuration.

125. **Urochromogen Reaction in the Urine.**—Weiss dilutes 1 part of fresh urine with 2 parts water and fills half of two test-tubes with the mixture. He then adds to one of the test-tubes 3 drops of a 1 to 1,000 solution of potassium permanganate in distilled water. In the presence of urochromogen, a yellowish tint develops, the intensity proportional to the diazo reaction.

126. **Blood-Pressure During Narcosis Plus Chilling.**—Stursberg reports experimental research on dogs which showed that under the influence of ether the application of cold caused a pronounced rise in the blood-pressure. When the dogs were under the influence of chloroform, there was no effect of this kind on the blood-pressure. These facts show that ether, in the dose necessary for general anesthesia, does not affect the vasomotor reflexes, while, on the other hand, chloroform evidently arrests this reflex action. In discussing the practical importance of these findings he compares the effect of ether in these experiments to that of "catching cold." Although the nature of "catching cold" is not fully understood, yet it is generally assumed that it is the result of the contraction of the vessels in the skin with consequent increased accumulation of the blood in the internal organs; in other words, it is the peripheral vascular reflexes which play the decisive part in the development of the "catching cold syndrome." Contraction of the vessels unless followed at once by a reaction of dilatation seems to be especially dangerous. The conditions are thus seen to be practically the same under the action of ether as from "catching cold:" the vessels contract under the influence of cold without the salutary reactive dilatation. This explanation harmonizes with the facts observed, namely, that the use of ether is followed by postoperative pneumonia, etc., much more frequently than when chloroform is used. The practical lesson from this research is that when ether is used great care should be taken to avoid cooling the skin at any point. He adds that this harmonizes with the conclusions of S. G. Davis, which he reached by another route, to the effect that postoperative pulmonary complications may be avoided by preventing any reduction of body temperature.

129. **Serotherapy in Hemophilia.**—Trembur describes the history of a girl with extreme hemophilia who was treated by rabbit serum. The child increased 17 pounds in five months and it was hoped that she would outgrow the tendency, but the onset of menstruation brought excessive losses of blood and although injection of 20 c.c. of rabbit serum had a strikingly favorable transient effect, the child succumbed to anemia. In a second case of hemophilia, in a boy of 9, the profuse hemorrhages were arrested at once by injection of 42 c.c. of fresh rabbit serum in two weeks. In both cases there was intense fetor ex ore for a few days before the onset of the hemorrhages. No by-effects were observed in either case; the favorable action of the serum is probably due to the leukocytosis which it induces. He warns, however, that the kind of serum used should be changed at the slightest indication of anaphylaxis.

133. **Prognosis of Extensive Resection of Small Intestine.**—Denk reports the ultimate outcome in fourteen cases in which over 3 and 4 meters (yards) of small intestine were resected, including one case from his own experience. All the patients who had not over one-half the total length of the small intestine resected, 3 meters, are in good health to date, from six to fourteen years afterward, but those with more extensive resection than this have all died with progressive marasmus.

- 144 Treatment of Postpartum Hemorrhage R Hofstatter.

138. **Tetany During Pregnancy.**—Frank has found it necessary to interrupt the pregnancy in several cases of tetany developing during pregnancy and advocates this procedure in the severer cases, especially when there is a tendency for the tetany to recur with different pregnancies. In most cases the tetany can be conquered with the bromids but it is not always possible to determine positively the inherently mild cases. *In four cases on record and in one of his own the tetany* was the direct cause of death.

139. **Ovarian Origin of Uterine Hemorrhage.**—Kaji states that in seven cases no cause for the hemorrhage could be discovered in or around the uterus, but in every instance, one or both ovaries were found pathologic. He is convinced that uterine hemorrhage may be due to influences from the ovaries in certain cases.

142 **Connection Between Myoma and Internal Disease**—Theilhaber reports seventeen cases in which uterine myomas coexisted with heart disease, contracted kidney or diabetes. The heart trouble was generally a myocarditis, and most of the patients were obese. He comments on the frequency of myoma in wealthy women, especially in Jewesses. The facts observed suggest that some metabolic disturbance with pronounced hyperemia of the uterus are the main factors in the development of myoma. There also seems to be a racial predisposition, and syphilis is certainly a predisposing cause He warns that a gumma in the uterus may simulate a myoma, while it might subside under mercurial treatment. It might be wise to apply the Wassermann test, he adds, to patients with myoma and inaugurate a course of antisyphilitic treatment in case of a positive response In conclusion he cites several cases in which there was slight cerebral hemorrhage with uterine myoma; Czerny has encountered five cases of paralysis with myoma.

145. **Lime Metabolism and Rachitis.**—Dibbelt reports research which, he thinks, explains the origin of rachitis as a disturbance in the lime metabolism leading to increased excretion of the lime salts into the intestine. The rachitic bone changes are the consequence of this general metabolic disturbance, as he explains in detail.

146-147. **Pathologic Importance of Stretching the Dura.**—Beneke explains the mechanism with which any pressure on the sides of the head of an infant may stretch the dura so forcibly as to entail venous stasis in the ventricle region. During delivery, pressure of this kind may tear the tentorium in a characteristic manner and this, he believes, if it is not immediately fatal, explains certain brain affections in later life. Pressure on the temples of the head from a child cadaver closes the foramen magnum by forcing part of the cerebellum into it. The condition is seen to be the same as with chronic hydrocephalus in which the cerebellum is forced into the foramen and the communication with the spinal canal is obstructed He found the tentorium lacerated thus in a number of children dying during delivery or soon after, even when the delivery had been rapid and easy, once even with a four months' fetus. The possibility that fatal asphyxia may be due to this cause with normal delivery is important, from both the clinical and medicolegal standpoints. Pressure on the temples of the decapitated head from a child cadaver is seen to stretch the falx as well as the tentorium, and thus it entails compression of the straight sinus which must induce venous congestion in the region of the tela and choroid plexus The same thing occurs when a child with still open sutures lies habitually on the side of its head; the weight of the brain alone has this effect of stretching the falx with the consequent tendency to venous congestion inviting hydrocephalus. Acute total occlusion of Galen's vein is liable to entail sudden death, as occurred in the case of a young man in Beneke's experience Rachitis or softening of the bones of the skull in older children may also favor the stretching of the falx and tentorium as the child lies on the side of its head and this may be the explanation in many cases of chronic hydrocephalus, as the straight sinus and the longitudinal sinus are both liable to compression from this cause, with chronic hyperemia in the region as the result. It is a familiar fact that in children with rachitis the brain is unusually heavy, evidently the result of a special hyperemia; this hyperemia is now explainable, he declares, as the result of the lengthwise stretching of the dura by pressure on the side of the head.

148 **Prevention of Laceration of the Perineum.**—Grube comments on the necessity for preventing the parturient from slipping away from the hand protecting the perineum during delivery. This he accomplishes by having her lie on her back, the shoulders being held by another person; a small cushion is slipped under the buttocks close to the anus, the feet are supported or the thighs are flexed on the abdomen. The obstetrician's right hand should be protected by a coarse cotton mitten. The diameter of the fetal head from brow to back of the neck is brought into the median line, the right hand pushing back the perineum with the thumb while holding the forehead firm with the rest of the hand. The left index and middle fingers, at the same time, are worked into the angle toward the symphysis, and lift up the back of the head until the back of the neck enters the symphysis angle. With this technic he has successfully delivered fifty-two primiparæ including five over thirty years old, there was laceration of the perineum in only four cases, and in one of these the laceration occurred during the passage of the unusually broad shoulders, the head having emerged without injury. The few lacerations that did occur were all small, of the first degree, and were readily sutured at once

153. **Puncture in Treatment of Gonorrheal Epididymitis.**—*Fruhwald* gives comparative series of patients with gonorrheal epididymitis treated with puncture and without, the results demonstrating, he declares, that the immediate effect of the puncture is often a great relief, but that it has no durable curative action. The indications for it are consequently limited.

Therapie der Gegenwart, Berlin

October, LI, No. 10, pp 433-480

- 158 *Duodenal Ulcer. (Zur Pathologie und Therapie des Duodenalgeschwurs) F Umber
- 159 *Treatment of Acute Infectious Diseases in Children. A. Baginsky
- 160 *Treatment of Asthma. O Weiss.

158. Duodenal Ulcer.—Umber remarks that duodenal ulcer must be more frequent than is generally recognized as in none of his cases had the diagnosis been correct when the patients were referred to him; at one time he had five cases at once in his service. At the same time he expresses some skepticism in regard to the Mayo's report of more duodenal than gastric ulcers in a recent series of 200 cases. The wall of the duodenum may be apparently intact when examined from without, and the symptoms often lead to false conclusions. The pains frequently simulate gall-stone trouble; one of his patients found relief by assuming the knee-elbow position during the attack. In this case the ulcer was in the rear wall of the duodenum and had become adherent to the pancreas. The pain seems to be dependent more on the quantity than the quality of the food. The stomach is generally functionally affected in sympathy. Treatment should be practically the same as for gastric ulcer unless profuse hemorrhages or unbearable pain demand operative interference. In one of his cases gastro-enterostomy alone did not prove sufficient to arrest the tendency to hemorrhage.

159. Treatment of Acute Infectious Diseases in Children.—Baginsky classifies the febrile cases in children in four categories: (1) those with a temperature between 40.5 and 41 C. (104 and 105.8 F.), but not of long duration; this is borne by children without much harm for a comparatively short time; (2) those in which the temperature fluctuates between 40 or 41 C. and 36 C. (104, 105.8 and 96.8 F.); this is the expression of septic infection and can seldom be influenced by antipyretic measure but only by removal of the septic focus; (3) cases with prolonged high temperature without much let-up, from 39 to 41 C. (102.2 to 105.8). This is especially dangerous for children. The fever is the expression of severe infection and, besides, exhausts the child's strength. If the fever keeps up for 5, 6, 8 or more days, it should be vigorously combated; the extent of surface on the child body ensures particularly favorable action with hydrotherapeutic measures for reducing the temperature; drugs should be avoided unless absolutely necessary. All antipyretic measures should be accompanied by tonics, and he regards wine as the best of these, and absolutely indispensable in infectious diseases in children, as it keeps their strength up owing to its complex composition, not solely by the alcohol content. He aims to keep the child's strength up during the febrile period with wine, milk, bouillon and raw eggs, believing that heart weakness in children is often the result of insufficient nourishment during the height of the disease. He prefers Greek wine or Bordeaux and sherry, giving from 25 to 100 gm. (½ to 3 ounces) daily to children from 5 to 14 years old. Even very sick children can be fed in this way and their strength and weight maintained so that they enter on a more favorable and shorter convalescence. Catarrhal conditions in the air passages and digestive tract and pathologic conditions of the kidneys are aggravated by defective functioning on the part of the heart, so that measures to keep the heart toned up act favorably on these other organs. Unless there is actual nephritis, elimination of toxins through the kidneys is promoted by subcutaneous injection (100 or 200 gm.) of a 3 to 1,000 salt solution, supplemented by alkaline mineral waters. Saline infusion is particularly useful also when diarrhea sets in; the diarrhea alone is frequently responsible for the serious collapse.

160. Treatment of Asthma.—Weiss endorses Brügelmann's explanation of asthma as invariably the result of irritation of the respiratory center, and his treatment based on this conception. Brügelmann has had 3,510 patients with asthma during the last thirty years, and has made a special study of the traumatic, reflex and toxic factors that may irritate the respiration center and thus induce asthma in the predisposed. The whole horde of reflexes may act on the respiratory center, reflexes from the eyes, ears, nose, throat, stomach, intestines, sexual organs, cold feet and skin, etc. The toxic action of the insufficiently oxidized blood, as with heart and kidney disease or after excessive exercise, dancing, running, etc., is a prominent factor in the development of the attack of asthma, but the greatest light was thrown on the whole subject, he asserts, by his observation of the effect of inhalation of an atropin spray. This frequently arrested at once an attack of asthma, as also painting the nasal mucosa with atropin-cocain solution. The special points where the atropin exerted this action seem to be restricted to the region behind the uvula, the tonsils and their vicinity. The asthma is at once arrested and there is no further disturbance as long as the paralyzing action of the drug on the region lasts, no matter whether the asthma is of traumatic, reflex or toxic origin. This, he says, confirms the assumption that this region is the seat of the spasmodic contraction and, further, that the morbidly irritated respiration center elicits this spasmodic contraction as its normal reaction. The aim in treatment should be to free the respiration center from the injurious influence of morbid reflex stimuli and the action of toxins; consequently all the organs must be examined to discover the source of the reflexes and all put in good order and functional affections cured. The asthma specialist must therefore be skilled in rhinology, gynecology, electrotherapy and pneumatotherapy and be a master of suggestion to cure the purely functional disturbances. But success in the end will well repay his efforts.

Wiener klinische Wochenschrift, Vienna

October 6, XXIII, No. 40, pp. 1403-1438

169 *Hepato-Duodenostomy. (Zur Chirurgie der Gallengänge.) Doberer.

163. Device for Ambulant Treatment of Fracture of the Patella, Olecranon and Calcaneum.—Fischer prevents the loosening of the adhesive plaster dressing with these fractures by a spring device which holds the ends of the plaster taut. It can be improvised with a piece of hard wood about 1 foot long, ¼-inch wide and ⅜ inch thick, with a spool fastened at each end. A cross-bar is stitched in the crossed ends of the adhesive plaster and a string from each passes over the spools at the end of the wood and is fastened to an iron ring. A rubber tube is used to tie the two rings together, the pressure applied being sufficient to bend the wood like a bow; this elastic pressure stretches the ends of the plaster with such force as to prevent any loosening. A similar device is made of two or three sheets of steel of the same shape, with prongs at each end to hold the crossed ends of the plaster dressing. This spring looks like a miniature wagon spring. There is no direct pressure on the limb but the device holds the stumps together with a permanent force that can be regulated, while the patient is able to be up and about. The joint can be moved under the spring device without spreading the stumps in apposition, thus obviating the danger of ankylosis. Another advantage is that the pressure is applied to the front of the fragments and thus prevents their tilting up. His article is accompanied by twenty illustrations showing the device as he has applied it in ten cases of fracture of the patella and in fracture of the olecranon or calcaneum. The diastasis was from 2 to 3.5 cm., but the fracture healed with consolidation of the bone and complete restitution of function in all the patella cases. He applies the plaster in three layers, slitting each part half way and spreading the slits to form a fan; a few stitches at the base of the slits holds them firm.

164. Tonsillitis During Tuberculin Treatment.—Krämer thinks that it is more than a mere coincidence that a process resembling follicular tonsillitis developed in sixteen out of seventy cases of various tuberculous eye affections in which the patients were being given tuberculin treatment. There was no apparent connection between the cases, either in time or locality, and tonsillitis is rare in an eye clinic, and none of the other patients developed tonsillitis. These facts suggested that the angina was a local reaction to the tuberculin, some tuberculous process in the tonsils flaring up. This assumption is sustained, he declares, by Reimann's discovery of foci in the tonsils in every patient at his sanatorium with tubercle bacilli in the sputum and also in 6 per cent. of all the others. Spengler has recently called attention to a reaction angina under tuberculin treatment. The brief duration and the lesser general indisposition distinguish this angina from ordinary follicular tonsillitis.

166. **Treatment of Sclerotic Paranephritis.**—Zuckerkandl calls attention to a special form of nephritis which requires a different treatment. The kidney becomes embedded in a fibrous mass of indurated tissue, and when this has occurred the organ has long since ceased normal functioning. It is generally small in comparison with the fibrous bed, but it is always completely destroyed, either by suppuration, induration or fatty degeneration. The discovery of the fibrous sclerosis around the kidney demonstrates that the organ within is profoundly degenerated, and often the seat of a latent process. Its removal is urgently indicated, but it is not necessary to remove the capsule. He has shelled out the kidney from its capsule in over a dozen cases of this kind, and the results have been constantly excellent, so that he commends this technic as the routine intracapsular nephrectomy procedure for fibrous sclerotic paranephritis. No harm, he says, results from leaving the indurated mass and the capsule.

169. **Hepato-Duodenostomy.**—Doberer gives an illustrated description of a case of bile fistula in which it was not possible to utilize the hepatic duct for drainage, and he consequently sutured the duodenum directly to the main intrahepatic biliary duct.

175 *Possible Dangers of Adrenalin-Saline Infusion. (Ist die Infusion von Adrenalin-Kochsalzlösung ungefährlich?) W. Merkens.

175. **Fatality After Adrenalin-Saline Infusion.**—Merkens' patient was a man of 50, with glycosuria for several years. The condition the day after an appendicectomy was grave but not hopeless, the pulse was 140, but regular, and there was occasional vomiting. One liter of physiologic salt solution was then infused into a vein in the arm, with ten drops of the ordinary adrenalin solution. The patient became pale and restless, a rigor soon followed, the pulse grew smaller and faster, and death ensued in a few hours. The adrenalin solution was not quite fresh; most of the contents of the bottle had been previously used, but the fluid was perfectly limpid.

180 Thyroid Treatment for Stimulation of Lacteal Secretion. (Der Milchmangel der Frauen, heilbar durch Thyreoidin.) A. Siegmund.

176. **Operative Enlargement of Infantile Vagina.**—None of the women in the three cases reported had vaginismus, and Josephson thinks that an anatomic basis for the latter could be discovered in many cases if sought for. In one of the women the smallness of the vagina was the result of cicatricial constriction, in the others it was a primary lack of development. His operation was a lengthwise incision carried through the vulva up into the vagina for about 3 cm., about a fingerbreadth on each side of the median line. The lips of each incision were then drawn sideways and sutured together again in such a way as to bring the incision across instead of lengthwise of the vagina. Between the two incisions is a stretch of intact vulvar mucosa, enlarging the vagina to this extent. The double incision respects the muscles better than a single incision, while the lumen is correspondingly enlarged. In one case he preceded the operation with progressive dilatation of the vagina, and in another he found three incisions necessary.

October 20, No. 126, pp. 1329-1336

186 Foreign Bodies in the Esophagus. C. Rusconi.

183. **Traumatic Neuroses.**—Mannini relates the particulars of a case which emphasizes the necessity for caution in examining and managing a patient after an accident. In his case one physician after another seems to have added his share of suggestion of symptoms and consequences of the trauma until the patient became an incurable invalid, presenting the clinical picture of a cerebellar disease and yet no anatomic cause could be found for the syndrome at necropsy. The aggravation of the syndrome after each visit to a physician was a noticeable feature of the case. Mannini warns that persons after an accident require the same circumspection and reticence on the part of physician as confirmed neurasthenics and hysterics. They are peculiarly liable to be affected by unintentional and even unconscious suggestion and imitation. This fact should be borne in mind in all intercourse with them, and it should also serve as a guide in treatment.

191 Favorable Action of Roentgen Rays on Experimental Tuberculous Joint and Gland Disease. F. Ghilarducci.
192 The Presystolic Murmur and the Duplication of the Second Sound in Mitral Stenosis. C. Pezzi.

187. **Cerebellar Tumors without Special Symptoms.**—In the case reported by Ceconi a young man had severe headache for six months with only occasional slight remissions. The headache involved the right parietal region, sometimes the whole right side of the head, or was diffuse, aggravated by movements or touch. During the last three months the vision had grown weaker, but there were no vomiting, vertigo or disturbances in the gait except slight weakness apparent in the left leg after walking. The knee-jerk was much exaggerated on the left side. The patient died forty days after entering the hospital, but there were no special cerebellar symptoms at any time. Necropsy revealed a large caseified tubercle occupying nearly the whole of the right hemisphere of the cerebellum, with a smaller tubercle in the center of the left. He discusses the differentiation of such cerebellar lesions and the localization of the tumor explaining the absence of ataxia

in some cases. Luciani's experiments have confirmed the assumption that other organs can vicariously substitute the lacking cerebellar functioning. Experience has also demonstrated that a gradually growing tumor may push the nerve fibers aside without really injuring them, so that normal functioning may long persist.

October 12, No. 41, pp 1153-1176

198 Treatment of Acute Appendicitis. A. Møller.

197. Simple Test for Sugar in the Urine.—Hasselbalch and Lindhard describe a new test which they say makes it possible for the busy practitioner without laboratory facilities to determine readily whether the applicant for life insurance, for instance, has pathologic proportions of sugar in the urine. Their technic dispenses with the necessity for removing the albumin beforehand, and the error from the "autoreduction" of the urine is less, they assert, than with any other of the usual methods, the alkaline solution of safranin used not being reduced by uric acid or creatinin. The findings with this and the ordinary tests in long series of normal and glycosuric persons are tabulated for comparison, all apparently confirming the reliability of the test and the keeping properties of the reagent. This is a 1 to 10,000 solution of safranin; it does not seem to be affected by alkalies or heat, but the tint changes on the addition of sugar, the deep red tint fading away and the colorless fluid then assuming a yellow or pinkish yellow tint or fluorescence. One c.c. of the 1 to 10,000 safranin solution and 1 c.c. of a 1 per cent. solution of potassium hydrate are mixed and the urine added drop by drop, after which the glass is placed in the boiling water bath for three minutes. The above mixture of 1 c.c. of each fluid reduces about 0.25 mgm. of grape sugar, from which it is easy to compute the approximate urine proportion in the urine. The test may be regarded as giving negative findings if the characteristic change of tint does not follow when ten drops of urine are added to a mixture of 3 c.c. each of the safranin and the potassium hydrate solutions and the whole is heated in the boiling-water bath for three minutes. Certain other sugars give the reaction as well as grape sugar.

Nordiskt Medicinskt Arkiv, Stockholm

XLIII, Surgical Section, Nos. 1-2. Last indexed, Nov. 12, p. 1772

199 *Kidney Stone. (Zur Diagnose und Therapie der Nephrolithiasis.) B. Flöderus. Commenced in vol. xlii.

199. Kidney Stone.—Floderus here makes a contribution to the study of nephrolithiasis, which he discusses from various points of view, his article embracing 261 pages, with summaries of fifty-six cases. The article is in German and is accompanied by sixteen plates and ten pages of alphabetically arranged bibliography. He remarks that in few surgical affections is the early and exact diagnosis more important for the ultimate outcome than with kidney stone. He discusses the Roentgen-ray findings and the sources of error from them, advising Roentgen examination after each attack of colic, and remarking that the stereoscopic picture is especially instructive in nephrolithiasis. If the size of the stone permits the likelihood of spontaneous expulsion, internal treatment is justified, as also in most cases in which the pain is bearable and the hematuria slight, but an operation may be considered earlier in the young and robust.

CHEVALIER JACKSON, M.D.
PITTSBURG, PA.

Four little children threatened with starvation because of a cicatricial esophageal stenosis due to the swallowing of some form of caustic alkali to which the laxity of our laws permitted them to be exposed were under my observation within a year. These four cases are my excuse for addressing you on this subject. The law requires that the druggist shall label corrosive poisons "Poison" and the careful druggist adds antidotal advice. Next door to the druggist the grocer sells corrosive poisons having on the label not only no hint of caution, but having directly misleading statements. such as "won't injure the hands," "will not harm the most delicate fabric," etc. One brand of concentrated lye is marked "Caution." When I encountered this I thought, "At last I have found one preparation on the market whose manufacturer has a conscience that compels him to give some advice protective to little children." Alas, the underwriting, "Be sure to replace the lid after using," was intended only to prevent deliquescence of the granulated contents.

It is the general impression that concentrated lye is a relic of the old days of home-made soaps, but investigation shows that it is in common use in the household for labor-saving cleansing of all kinds. Its harmful effect on the hands conveys to the thoughtful some hint of the caustic nature of its contents. But the frequency with which patients with esophageal stricture, following the swallowing of concentrated lye, come in an almost fatal state of inanition to the esophagoscopist is an index to the thoughtlessness of the users of concentrated lye, and an urgent call for legislation that shall compel the manufacturer to label concentrated lye containers "Poison" and to state a few antidotes, even if this does diminish slightly the sale of such products.

Esophageal stricture from the swallowing of commercial lye has been for many years a lesion of common observation by those interested in the esophagus. The frequency declined with the more general substitution of cheap commercial soaps for the home-made product: but concentrated lye is still in extensive use for general scrubbing and cleansing purposes. Furthermore, strictures of the esophagus are again on the increase owing to the flooding of the market with a large number of proprietary "cleansers" for household use and "washing powders" for laundry use.

I have seen three cases of the most severe ulceration and sloughing of the esophagus from the swallowing of *strong solutions of three of these proprietary preparations.* I have had the preparations analyzed and all contained similar ingredients: an abrasive, a strong powdered soap, and a caustic alkali—soda ash. The proportions varied from 8 per cent. in the cleaners up to 40 and 50 per cent. in the laundry powders; but in none was the corrosive alkali so diluted as not to be caustic to the delicate esophageal mucosa of a child. And worst of all, the mixture was not thorough; therefore some portions were more concentrated than others. so that under certain conditions it would be possible for a child to get a concentrated dose of caustic. *Another thing* which doubtless contributes to the danger is the insoluble nature of the abrasive and the slower solubility of the soap. Thus a little water dissolves out the alkali in strong solution.

The accident in one case I have seen occurred through the child's swallowing the rinsings of the almost empty can. The economical mother was endeavoring to extract the dregs for use; and, totally unsuspicious of a preparation which could not "injure the most delicate fabric," set down the can within reach of the child. In another instance the cleansing powder had been sprinkled on the dishes in the dish-pan. From one cup it was not removed by rinsing, the powdered soap in its composition making it adherent, and from this cup the child drank. In the third instance the child drew water from a faucet into a cup that had been used to measure out a quantity of a proprietary washing powder for laundry use.

On not one of the containers of these three widely advertised proprietary caustic preparations was there *one hint of the dangerous nature of the contents.* There was no word of advice that some vinegar or oil or milk or cream might lessen the likelihood of the child dying of the agonizing burns, or the subsequent ulcerative esophagitis or stricture. On the contrary, the most misleading statements as to the harmlessness of the preparations are on every package, in every magazine, in every street car. One manufacturer's agent to whom I spoke said: "Why, if we labeled our goods 'poison' and gave an antidote nobody would buy them." Comment is unnecessary.

My reason for bringing this matter before this section is the hope that some of you will take the matter up and see that the laws that compel the druggist to label corrosives that go into the medicine closet "poison" shall likewise compel the manufacturer so to label the corrosives that are infinitely more dangerous because they go into the kitchen. Considering the cosmopolitan character of our population, and especially of our domestic servants, the caution label should be in many languages.

---

* Chairman's address before the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, St. Louis, June 7-10, 1910.

If the existing laws do not apply to the grocer as well as to the druggist, then, you doubtless all agree with me in the opinion that the laws should be amended. I leave this to those better able than I.

In conclusion, I beg you to look into your own kitchens and find whether or not caustic alkalies are used with a reckless disregard of their poisonous nature.

1018 Westinghouse Building.

CHANGES IN THE NOSE AFTER WIDENING THE PALATAL ARCH *

L. W. DEAN, M.D.
IOWA CITY, IOWA

For some time we have known that widening the palatal arch resulted in widening of the nasal chambers. At least, we have had every reason to conclude this from the reports of many patients regarding the great improvement in breathing after this had been done. I am sure that all are familiar with the work of G. V. I. Brown and Nelson Black on the improvement in breathing of patients with contracted nares after widening the arch; also the influence it has had on the straightening of deviated septa.

In 1908 I showed before this Section by actual measurement the increase in the breathing-space of the nose in green skulls after widening the palatal arch. So far as I have been able to determine, these measurements have not been reported as having been made on a living subject. As there is still some skepticism regarding the increase of breathing space by widening the palatal arch I wish to report the measurements of a case.

As long as we depend on patients' expressions regarding their improvement there may be a slight basis for doubt. With the actual measurements before us there can be none. This method of measuring has been the result of several years' work. It has been tried repeatedly with constant results, on patients on whom no work has been done. To measure the nose I use a septimeter (see illustration) devised by myself for this purpose.

I will give the history and measurement of one case only, as that will serve as an illustration. I made no measurements myself; all were made at my request by Dr. W. F. Boiler, assistant rhinologic surgeon to the University Hospital, because I wished them to be made by one not interested in the results.

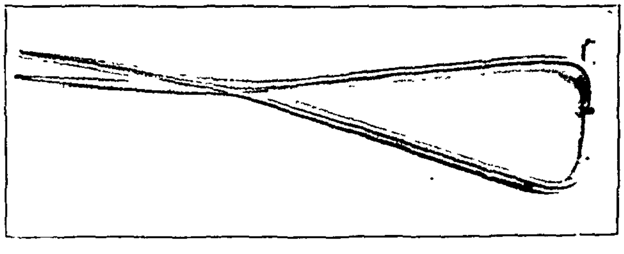
All measurements were made under the same conditions: namely, with the mucous membrane shrunken by continuous application of cocain 20 per cent. and adrenalin 1 to 1,000 for twenty minutes.

Patient.—Miss L. D. Y., aged 8, referred by Dr. Jones, of Kalona, Iowa. The patient gave a history of being a constant mouth-breather. She could not remember ever having been able to breathe through her nose. She suffered very much from temporal headache. This was not influenced by use of the eyes. The attacks of headache were not periodic. The headache was made worse by taking cold. She took cold very easily.

Examination.—Patient was very dull mentally. The face was narrow, owing to poor development of the superior maxillæ. The nose was very thin. The turbinates were normal in size but pressed tightly against the septum. On the right side was a medium-sized posterior spur.

Treatment.—It was a typical case of the nasal breathing being impossible because of the nose being too narrow, not because of pathologic tissue. The spur was removed. Two months later nasal breathing was little better than at first. The palatal arch was exceedingly high and narrow. As the turbinate tissue was normal there could be no excuse for removing it, entire or in part, so I asked Dr. G. V. I. Brown to widen the arch. Expansion bands were fitted to the teeth on each side and attached with rigid metal bars. Across the mouth a tube attached firmly to the connecting bar upon one side, fitted over a threaded bar, also solidly attached to the bar on the opposite side. A nut was adjusted, which when turned made pressure across the mouth. The appliance was cemented into place and when finally adjusted, was so arranged that pressure was applied directly across the palate at its narrowest portion with resistance against all the teeth from the cuspids to the molars upon each side. When the maxillary bones had been sufficiently separated and the nose correspondingly widened, an appliance was adjusted with a screw, nut and tube by which pressure was exerted from before backward. When the arch had been sufficiently lengthened on this side to admit it, the teeth which had previously occupied a portion of the palate, were drawn outward into proper line.

In the accompanying table are three sets of measurements: Column A shows the measurements before widening was begun; Column B, the measurements made during the widening process; the measurements in Column C were made after the widening was completed. The measurements are expressed in units as measured in the handle of the septimeter.



Septimeter for measuring the nose.

MEASUREMENTS BEFORE, DURING AND AFTER THE WIDENING PROCESS MAY 28, '09.

	A.		B.		C.	
	R.	L.	R.	L.	R.	L.
Anterior end inferior turbinate to septum.. ...	5	6	8	9	9	10
Middle inferior turbinate to septum	5	4	7	6	7	6
Posterior end inferior turbinate to septum......	10	12	10	12	12	12
Anterior end middle turbinate to septum.......	2	2	2	3	4	4
Middle middle turbinate to septum	1	2	2	2	2	4

Result.—The subjective improvement of the patient was the very best. She spoke of breathing comfortably for the first time during her life. The objective improvement was very manifest. She is now a nasal breather both by day and night. Her general health is better. She is certainly wonderfully improved mentally. Her face is broader.

The figures show that the widening effects the nose throughout antero-posteriorly. Also the middle meatus is affected as well as the inferior. Consequently the sense of smell should be benefited. I regret very much that observations along this line have not been made.

These measurements corroborate the measurements that were made on a green skull and reported to this Section two years ago.

ABSTRACT OF DISCUSSION

DR. EUGENE S. TALBOT, *Chicago:* These measurements show the actual conditions present when the dental arch is spread. One important point which should be emphasized is that the turbinates are not destroyed. While I am not a rhinologist, it seems to me that that is the last thing which should be done. The dental arch should be spread first, and then if the rhinologist thinks there is plenty of room the operation should not be undertaken. It is important that as much mucous surface should remain in the nose as possible.

---

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

Dr. M. H. Fletcher, Cincinnati: In my own mind there is a question as to the solidity of the tissues when pressure is put on them. A suture, particularly of the skull, is particularly strong in its indentation. Is it always sure that division will occur in the suture between those two bones and divide in the nose? Have any of you had any experience in having separation at any other place than where you desired? It is impossible for us to see the thickness of the bone. I can conceive of a case of very heavy bones, in which there would not be separation in the proper place. Have any of you had any such experience? I should be glad to have any light on the question whether or not a separation at any other place than the suture would have a good or a bad result. Separation must come on one side of the septum or the other, must it not?

Dr. G. V. I. Brown, Milwaukee, Wis.: No, the ideal condition is separation between the central incisors. In view of the fact that the premaxilla is completely divided from other divisions of the superior maxilla in early life, it is curious that ossification becomes so complete on each side, and the median suture so marked. There is no longer a question as to where and how the maxillæ separate. One of the questions evidently applies to those cases in which the suture is dovetailed. My own opinion is that under such conditions the little interlocking portions of the suture are fractured.

In some few instances we have not had the outward and visible sign of maxillary division, which of course is indicated by separation of the incisors. In those cases we have usually had good results also, but they were not such unusual types as Dr. Dean's patient. Sometimes I think that the premaxilla does not always unite in exactly the same way, because the separation occasionally appears between the central and lateral instead of between the two centrals. This ultimately readjusts itself, because an increase on one side gives more freedom for the septum to adjust itself.

Dr. L. W. Dean, Iowa City, Iowa: I do not like to theorize in this matter, so far as changes in the nose are concerned. It has not been worked out completely, and I am afraid Dr. Brown and I would not agree as to how we get straightening of the septum after widening the arch. Work is being done, and a year from now it will be more definitely decided. I think this patient is going to have more breathing-space a year from now than she has at present. When I saw this patient after the first widening had been done, I could put a lead-pencil in between the incisors in front. I hastily wrote to Dr. Brown and got a letter from him that he was ready to have these teeth brought together. This was done very nicely. We have widened the arches of skulls of subjects over 40 years of age. They have all opened along the median line.

AN APPARATUS FOR SUPPORTING AND HOLDING THE HEAD AND SHOULDERS IN CEREBELLAR AND HIGH SPINAL OPERATIONS

HOMER B. SMITH, M.D.
FARGO, N. D.

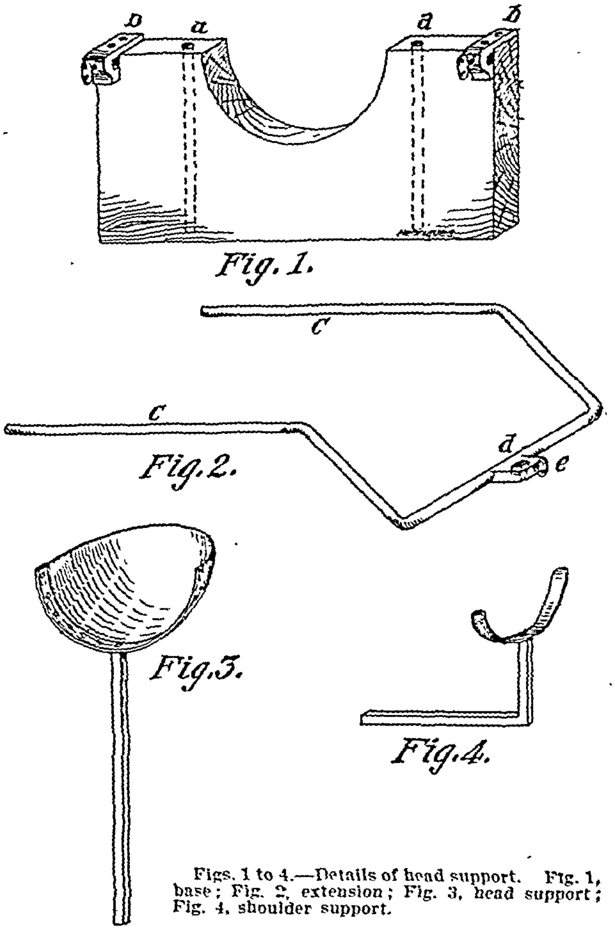
The difficulties attending suboccipital and high spinal operations are largely due to the depth of the cerebellum and cord. Access to these parts is not easy on account of the difficulty of holding the patient's head and shoulders in a position that will allow a fixed field of operation, and at the same time not interfere with the patient's respiration and the administration of the anesthetic. This is especially true in trephining over the cerebellum with the patient in the prone position.

I devised the apparatus here described to obviate these difficulties. I first demonstrated its usefulness at the Boston Children's Hospital in an operation for cerebellar tumor. The satisfactory use to which this simple apparatus has been put in the past two years by various Boston surgeons, both in operations for cerebellar exploration and cervical laminectomy, leads me to believe that as an aid in these operations the apparatus is worthy of mention.

DESCRIPTION

Figure 1 gives details of the head support. The apparatus consists of a base (Fig. 1), an extension (Fig. 2), a head support (Fig. 3), and two shoulder supports (Fig. 4).

The base (Fig. 1) is an oak plank, 17 by 8 by 1¼ inches. A semicircular piece, 8 inches in diameter, is cut out in front. There are two one-half inch holes, bored through the width of the plank 10 inches apart (a, a). These are to accommodate the extension. There are two set-screws, one at either corner in front (b, b), to receive the shoulder supports.



Figs. 1 to 4.—Details of head support. Fig. 1, base; Fig. 2, extension; Fig. 3, head support; Fig. 4, shoulder support.

The extension (Fig. 2) is a three-eighths-inch iron rod, 48 inches long, so bent as to form two horizontal arms 18 inches long (c, c), and a transverse rod (d) 10 inches long. The horizontal arms are bent downward at an angle of 45 degrees 13 inches from the ends. At the center of the transverse rod is a set-screw (e) to receive the head support.

The head support (Fig. 3) is a three-eighths-inch square iron rod 12 inches long, to one end of which is attached a semicircular piece of iron 7 inches in diameter and one-half inch wide. To this iron is riveted a heavy piece of mill-board which has been molded to make a quarter sphere.

The shoulder supports (Fig. 4), two in number, are three-eighths-inch square iron rods 10½ inches long, and bent at right angles 7 inches from the ends. To the short or upright arms are attached semicircular pieces of iron one-half inch wide and 4 inches in diameter.

In use the head piece is covered with a sterile towel and the shoulder pieces are padded and bandaged. The apparatus is attached to the ordinary wooden operating table by two iron clamps.

The head piece, extension and shoulder pieces permit wide adjustment. The head of the patient can be raised, lowered, extended or flexed, and the shoulder pieces can be adjusted laterally to conform to the width of the patient's shoulders.

The illustration (Fig. 5) shows the apparatus complete. The diagram (Fig. 6) shows the position of a patient for operation.

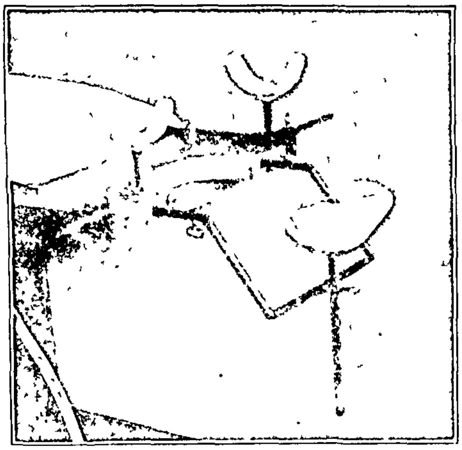


Fig. 5.—Apparatus complete.

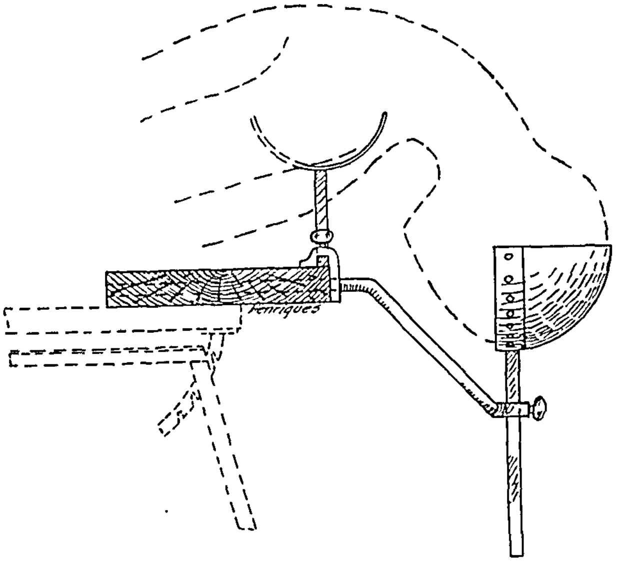

Fig. 6.—Diagram showing position of patient during operation

THE ADVANTAGES OF THE APPARATUS

The head of the patient is held in such a position as to afford a firm, immovable base against which to work.

The patient's chest is supported, allowing free respiratory movements.

The anesthetist is relieved of trying to do two things at once, namely, to hold the patient's head and give the anesthetic.

The apparatus is simple, has a wide range of adjustability and is cheap. It could be made lighter and could be more beautifully finished, thereby adding to its cost without in any great degree increasing its efficiency.

ENTEROPTOSIS, WITH SPECIAL REFERENCE TO ITS ETIOLOGY AND DEVELOPMENT

AND REMARKS ON THE RESULTS OF EXAMINATION OF FOUR HUNDRED WOMEN WITH REFERENCE TO THIS CONDITION *

RICHARD R. SMITH, M.D.
GRAND RAPIDS, MICH.

The literature dealing with enteroptosis is a most voluminous one and I shall attempt nothing but a brief review of it. The subject is so unusually complex and presents so many different phases that it has led to much theoretical discussion, much of which has proven to be of little value. Our real advance and the best papers have come from those who have based their opinions on actual observations.

To Glénard,[1] who in 1885 published his paper which to-day is a classic, belongs the credit of calling the attention of the profession to the existence of this condition. Glénard believed that the whole trouble came from a sinking of the hepatic flexure of the colon. From this conception he built a most elaborate theory, which we know to-day has but little on which to stand. Glénard, however, recognized the type of individual in which enteroptosis was found and his description of it remains a classical one.

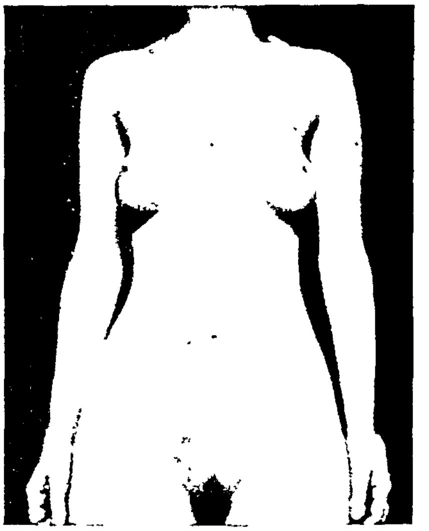

Fig. 1.—Typical enteroptotic figure. Fairly well-nourished. Muscular sufficiency poor. Thorax depth 17 cm., width 17.5 (!), index 94.5 (!), height 153 cm. (5 ft.), weight 94 lbs. Right kidney palpable; lower pole of stomach below umbilicus (gas). Pain in right side, well-marked neurasthenia. Note small size of thorax as compared with pelvis; small, long waist.

For five years after this the discussion remained confined to the French literature. In 1890, however, Ewald,[2] in a thoughtful and conservative article, brought the matter before the German profession. He gave Glénard credit for his discovery, but criticized many of his conclusions.

Stiller,[3] in 1896, pointed out the hereditary character of the condition and elaborated his floating tenth rib

2. Ewald, C. A.: Ueber Enteroptose und Wanderniere, Berl. klin., Wchnschr., 1890, xxvi, 277, 304.

3. Stiller, B.: Ueber Enteroptose im Lichte eines neuen Stigma Neurasthenicum, Arch. f. Verdauungskr., 1896, ii, 285.

idea, which is often cited to-day. The profession has not verified the close association which Stiller seems to have found between enteroptosis and a floating tenth rib, but is inclined to look on it as an anomaly often occurring, to be sure, in the habitus enteroptoticus, but as well in other individuals and of too uncertain a connection to place much stress on. Stiller's two articles, however, reflect a most careful study and observation, and his work will always stand preeminent in the history of enteroptosis.

Perhaps the next most notable piece of work done was that of Mathes,[4] who, although particularly interested in the mechanical conditions leading to prolapse, gives a most excellent description of the habitus enteroptoticus and the body form and calls particular attention to the general nature of the trouble. Mathes' article is also based on four years of study and observation and marks a distinct advance in the study.

An article by Albu[5] last year repeats and endorses much of what Mathes has said and is an excellent and useful piece of work. Albu has apparently fallen into error, however, when he concludes that because the kidneys and livers of a large number of new-born infants are palpable, the visceral prolapse itself is congenital and exists from childhood up. To this Butler, in a paper based on a study of one hundred and fifty-five children, has called attention.

An article by Martin,[6] of Chicago, and one by Vietor[7] are well worthy of citation, since they reflect a belief that the condition points to an arrest in the development of the embryo or a reversion to a lower type.

My own interest in the subject began some five years ago and was considerably stimulated by Mathes' article. I began examining, as a matter of routine, whenever practicable, the women who came to us. Most, but not all of them, presented symptoms referable to the pelvis or abdomen. I have examined formally over 400 such women and casually many more. After the usual pelvic and abdominal examinations, the weight, height, amount and condition of adipose and muscular tissue were noted and the form of the thorax and abdomen. I then obtained the index of Becher and Lenhoff and sought to palpate the kidneys. In the standing position, the form of the trunk, back and abdomen were observed and with the pelvimeter the depth of the chest at the end of the sternum and the width at the waist line were measured. I noted also the epigastric angle and the downward slant of the lower ribs. Lastly, the stomach was dilated and, in a prone position, its lower border, as obtained by this method, was recorded. In a considerable number photographs were obtained or other special examinations made. The mass of figures obtained became long since rather unwieldy and of but moderate value for statistical purposes. The study, however, has been a most interesting one and has yielded much that has been of

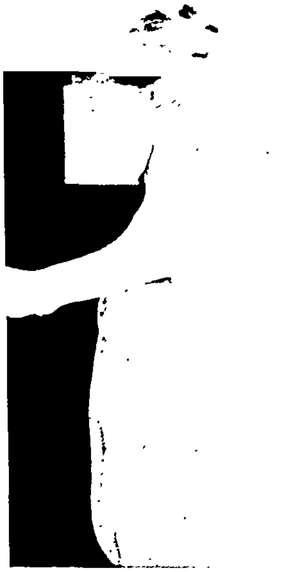

Fig. 2

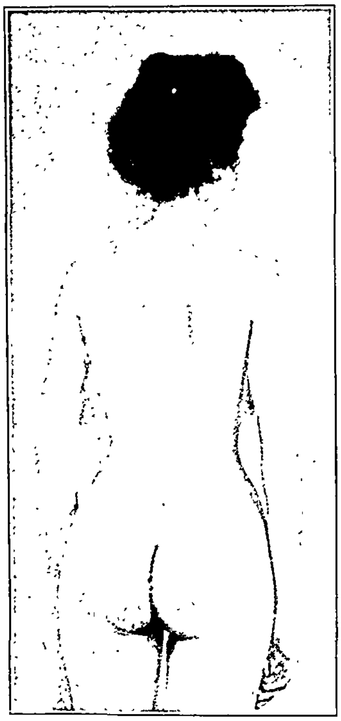

Fig. 3

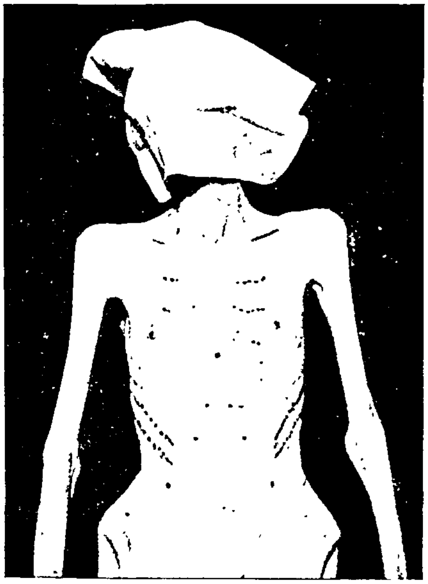

Fig. 4

Fig. 2.—Enteroptotic figure of very marked degree. Marked ill nutrition; marked muscular insufficiency. Thorax depth 13 cm. (!), waist breadth 20 cm., index 97 (!), height 147½ cm. (4 ft., 10 in.), weight 74 lbs. Palpable right kidney, lower pole of stomach in pelvis and very marked prolapse of colon (x-ray). Marked digestive disturbance, extreme and apparently hopeless neurasthenia. Note slenderness of form, extremely poor nutrition, marked lack of lumbar lordosis, rounding of shoulders (but fairly sufficient anterior abdominal walls), also smallness and collapse of chest, downward slant of lower ribs and long neck.

Fig. 3.—Typical enteroptotic figure, fairly well-nourished, little muscular insufficiency, palpable right kidney, lower pole of stomach two inches below umbilicus (gas method). Has good health. Note size of thorax and waist as compared with pelvis. Thorax depth 15 cm., width of waist 18 cm., index 88., height 170 cm. (5 ft., 6¾ in.), weight 116 lbs.

Fig. 4.—An enteroptotic figure with extreme emaciation, shown simply to bring out certain points referred to in text. Note small collapsed thorax, the sharp epigastric angle, the wide intercostal spaces above, the ribs lying close together below and slanting sharply downward and inward; the small waist with corresponding small upper abdominal cavity. Patient presents marked physical weakness, disturbances of many functions and is otherwise apparently a hopeless neurasthenic.

value to me. Above all, it has served to give more accurate information as to the relationship existing between the various phenomena presented by the condition under discussion. In many phases of the matter, as in those that have been the special subject of our inquiry, I realize there is still much hard work to be done. The problems presented are most intricate, and I believe that little real advance will ever be made in them by theorizing or speculation.

The *x*-ray played a considerable part in my earlier study. With Dr. Henry Hulst,[8] under the bismuth meal and the *x*-ray method, I studied some forty or fifty women; and, although perhaps this feature of the work was not exhaustive, it served to establish definitely the relationship of body form to the prolapse of the viscera and to revolutionize our ideas as to the position and form of the stomach and intestines. In an earlier publication[9] are given the results of the *x*-ray examinations we had made up to that time and I have not materially changed my ideas since then.

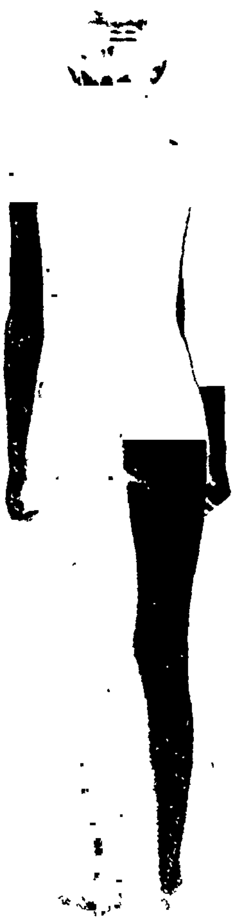

Fig. 5.—Typical enteroptotic figure of adult form in child of 12 years of age. Very poorly nourished, muscular insufficiencies well marked. Height 152 cm. (4 ft., 11½ in.), weight 73 lbs. (73!), thorax depth 14½ cm., waist breadth 17 cm., index 85. Right kidney palpable, lower pole of stomach ½ in. below umbilicus. Frail nervous child, otherwise in good health. (Left kidney had been recently removed for injury.) Note slenderness of form, lack of adipose tissue, small slender muscles and small thorax.

From early observations I soon learned that the two terms "congenital" and "acquired," as belonging to the two supposed types of enteroptosis, were far from satisfying: the one varies from the other not only in the matter of etiology but in many other of its manifestations. The division, I believe, is apt to convey a wrong impression. I wish to discuss the acquired form briefly a little later and in its place, but for the present and for clearness it would seem best that it be put aside and that we deal simply with the true or essential condition.

It may be well first to give a brief description of the enteroptotic woman (Figs. 1, 2, 3, 4.) The first impression one gets of such a woman is that of frailness, expressed in the contour of her form and often in her features. She is slender and has but little adipose tissue; her form is angular; her muscles are thin; there is almost invariably a perceptible laxness and softness of her tissues. She impresses one as being underdeveloped and lacking in vigor. These may be designated as fundamental characteristics. Associated with and largely dependent on these characteristics, one notes in such an individual that the neck is long, the chest undersized and showing distinct signs of collapse; that is, it is shallow, the upper ribs far apart, the lower ones slanting downward and inward and lying close together, and there is a distinct lessening of the capacity of the thoracic abdomen. The abdominal muscles are soft and lack resistance (muscular insufficiency) and there is a tendency for them to bulge forward. This bulging is rarely present to any marked extent in the nullipari and in a large number of cases it is practically lacking altogether. In the parous woman it is oftener present.[10]

The changes in the chest and upper abdomen above noted take place, largely at least, during the growth of the child to maturity—they are the permanent changes; at least, they are the most difficult of any material correction. These women are peculiarly apt to suffer from muscular insufficiency. We see it very apparent in the lessening of the lumbar lordosis, in the rounding back, the forward droop of the shoulders and, not infrequently, in weak-foot. The last-named important changes in body configuration, due to muscular insufficiencies, are by no means always conspicuously present and are to be looked on, generally speaking, as signs of fatigue. They are less permanent in character and are frequently materially bettered as the woman improves in health. I have not been able to note any marked differ-

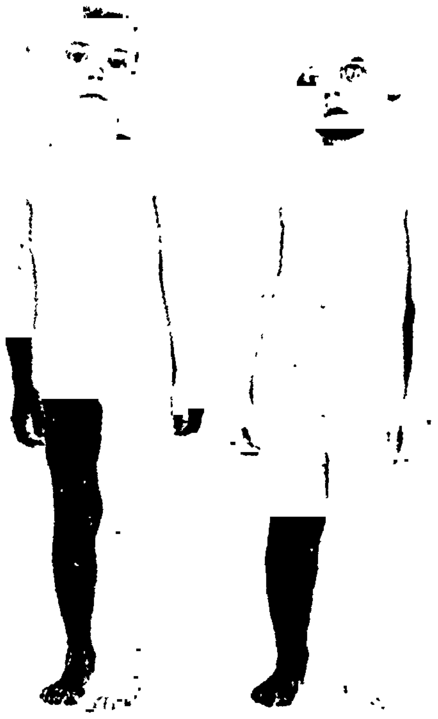

Fig. 6.—Figures of children, each 5 years of age. The one is frailer, less vigorous, less well muscled, less fat than the other. Shown to illustrate the type which we find in the history of the enteroptotic woman.

[9] Smith, R. R.: Enteroptosis, with Special Reference to the Body Form: The Mechanical Conditions Governing the Abdominal Organs and the Use of the X-ray in Demonstrating Stomach and Intestines, Surg., Gynec. and Obst., 1906, iii, 130 (discussion).

[10] The popular close association between enteroptosis and the size of the abdomen must be somewhat modified. The most marked prolapse often occurs in an abdomen that is nearly flat, and a bulging abdomen often encloses organs fairly well in place.

ence in the height of these women, although Mathes speaks of them as undersized and Albu as taller than others. One sees them short or tall, as are the more vigorous ones. In weight they are decidedly lacking, owing to the want of adipose tissue and the slenderness of other body structures.

In forming an estimate of the degree of body abnormality, I have laid some little dependence on the depth of the thorax (measured with pelvimeter from lower end of sternum directly to back). In doing so the height of the individual must always be taken into consideration. The depth ran from 13 to 17 cm. in enteroptotic women and from 16 to 20 cm. in the more vigorous ones. The relative capacity of the upper abdomen was obtained by securing the measurement above mentioned and combining it with the width of the waist. The index of Becher and Lenhoff, obtained by dividing the jugulo-pubic distance by the circumference of the waist and multiplying the result by 100, is also of much value in making this estimate. The higher the index the smaller the capacity of the thoracic abdomen and *vice versa*. The size and form of the thorax and abdomen as seen and estimated externally will indicate closely the position of the abdominal viscera. One should note also the amount of adipose tissue in and about the abdomen, the condition of the body musculature and the retentive powers of the anterior abdominal wall. With these noted and with a little experience one may determine very closely the position of the viscera as a whole. One will find the prolapse of this or that organ sometimes varying considerablly in relation to that of others, and he must not expect to make such estimates with mathematical exactness, but it is nevertheless true that the position of the viscera, as determined by palpation, percussion or the *x*-ray, corresponds very closely indeed to the outward signs above noted. The downward slant of the lower ribs and the epigastric angle (formed by the edge of the ribs, its apex being the lower end of the sternum) are useful and convenient signs in determining the collapse of the thorax and the size of the upper abdomen.[11]

In making a general estimate of the individual, however, relative to the enteroptotic habit, no one sign or condition should be entirely relied upon. It is practical to consider the amount of adipose tissue present, the condition of the musculature, the size and depth of the thorax, the size of the thoracic abdomen, the position of the viscera and perhaps, above all, the stability of the nervous system and any signs of its failure in normal function.

In speaking of enteroptosis one must distinguish clearly between the physical condition and the symptoms which the enteroptotic woman frequently develops. It must be recognized definitely that enteroptosis and good health, as we ordinarily speak of it, are not necessarily incompatible. We see

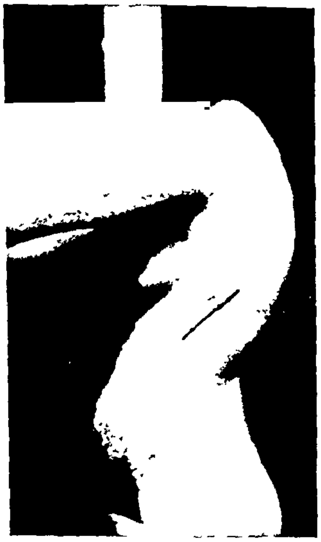

Fig. 7

Fig. 8

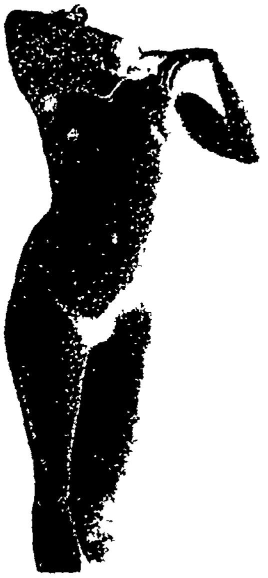

Fig. 9

Fig. 7.—Typical enteroptotic figure of the so-called acquired form, fairly well-nourished, muscular insufficiency well-marked. Thorax depth 17.5 cm., breadth of waist 22 cm., index 75. Right kidney palpable, lower pole of stomach above umbilicus (gas method). Marked digestive disturbance, pain in right side, neurasthenia. Note good size of thorax, low index, bulging anterior abdominal walls and rounding back (muscular insufficiency).

Fig. 8.—Statue of Venus de Milo. An ideal figure in Greek art, illustrating perfection in development and vigor. Note the muscular development, the large deep thorax, the capacious middle zone of the trunk. One finds that women approaching this ideal have organs in normal position. Compare with enteroptotic figures.

Fig 9.—Picture from Stratz. Figure of a vigorous woman, the opposite of the enteroptotic one Note well-nourished body, with sufficient adipose tissue, also the size and depth of thorax. The waist is large, corresponding to capacious upper abdomen.

---

11. As to the mechanical conditions producing prolapse, we note in such women certain conditions present: First, the lack of fat, which diminishes the volume of the abdominal contents and changes the contour of its cavity; second, the marked diminution in the size of the thoracic abdomen; and third, a laxness or hypotonus of the tissues of all the abdominal walls. The diminution in the size of the upper abdomen seems unquestionably due to a lack of usual strength or tone in the semirigid walls—call it muscular insufficiency if you will. The diminution in size becomes in turn a factor in the visceral prolapse. I may not here discuss the individual organs; suffice it to say the prolapse of each is evidently modified by the strength and mechanism of the structures which limit its motion. They are variously affected by the conditions named above. This matter of the mechanical cause is one about which there has been a great deal of speculation and little exact experiment or observation and I hesitate to enter into it. The factors I have mentioned seem to me, after a considerable study of the subject, those primarily concerned when considering mechanical causes and which I think must be fully considered in any argument on this phase of the subject. I should like to go into the many other theories advanced if time permitted.

constantly about us women of the most marked type who are in excellent health in the usual meaning of the term. They feel well, are free of pain and are able to take their places in society. As a class, however, they show less resistance to the strains of life than more vigorous women. Overwork, care and responsibility, indoor living, frequent child-bearing and poor food all bring enteroptotic women quickly to a state of fatigue, a lowered state of nutrition and an abnormal mental condition. With a few of them—the most exaggerated ones—the symptoms seem permanent and impossible of material alleviation. With many others the line between a satisfactory equilibrium and the existence of symptoms is narrow; the slightest strain is sufficient to disturb it. The symptoms that an enteroptotic woman develops are fairly well defined—pain in the back and groins, a feeling of weight and bearing down in the lower abdomen, disturbances of digestion, menstruation and urination, and a long series of disturbances psychoneurotic in character. It may, in fact, be said that the enteroptotic woman, when once her equilibrium is disturbed, develops symptoms principally neurasthenic in character. Perhaps, however, they should not all be classified as such. The pain above referred to should, I believe, be ascribed largely to the muscular fatigue and, occasionally perhaps, to the strains and secondary phenomena which a faulty attitude induces.

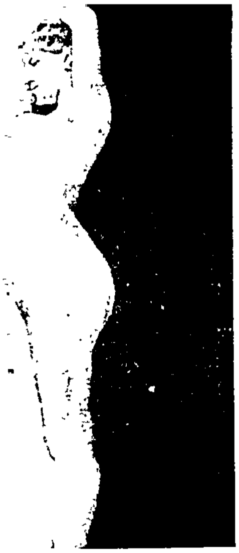

Fig. 10.—Picture from Stratz Figure of vigorous woman. Note the well-developed, well-nourished, muscular body, also the lumbar lordosis and size of the thorax.

In the study of enteroptotic women one early asks the question as to what part the prolapse of the organs themselves plays in the symptomatology; it is not uncommonly assumed that they are directly responsible for the pain, nervousness, disturbed function and ill health of the woman who has them. Here is a mechanical defect —what more simple than that it should cause the woman's symptoms? That this hardly reflects the truth is easy to determine. If we analyze the matter we find that, associated with visceral prolapse, we have first disturbances of digestion and, second, a feeling of weight and bearing down. In a large percentage of our cases at least, disturbances of function have plainly followed exhausting influences and are, I believe, to be regarded as symptoms of them. Although such disturbances occur very frequently in enteroptosis, they are of the same general variety as those seen in other neurasthenic women. Nervous exhaustion is, I believe, the immediate cause of the disturbed function; at least, in most instances, and I have found it to correspond to such exhaustion rather than to the degree of prolapse. It is not, I am convinced, due in the vast majority of instances to any mechanical obstruction—for example, the inability of the prolapsed stomach to evacuate itself because its lower pole lies low in the abdomen, or of a colon to evacuate itself simply because of its position. One frequently sees women with stomach and bowels prolapsed to a marked degree whose digestions are to all appearances good. The x-ray ordinarily shows no definite signs that may be safely interpreted as mechanical obstructions of the alimentary canal, nor does examination at operation show hypertrophy or dilatation, such as one would expect as the result of such obstruction. It is, however, perfectly possible that certain secondary changes may take place in such a colon as may cause abnormal function, but this I believe is not the rule.

The prolapsed organs do not ordinarily cause the pain referred to above. In a state of exhaustion it is common for the enteroptotic woman to have pain which is usually assumed to be caused by a dragging of the viscera on their attachments. The thought lies near that the pain is due rather to an insufficiency of the trunk muscles. This is one of the points in the study that will bear further investigation. Mere expression of opinion cannot, of course, decide it.

In a study as to the cause of prolapse one naturally asks the question when in the life of the individual it began. I have questioned some 300 women carefully in regard to the state of their nutrition and health during childhood and, although it would be almost impossible to classify satisfactorily the answers obtained, I have gathered from them certain facts. The enteroptotic woman of pronounced degree may always trace certain primary characteristics—namely, the lack of nutrition and vigor—to her childhood (Figs. 5 and 6). It is unquestionably a fact, then, that the frail, thin, weakly girls, who remain so during much or all of their childhood, become later enteroptotic women. In a vast majority of cases the anomaly may be traced with directness to a similar bodily condition in her immediate progenitors; that is, there is here a fixed hereditary factor of considerable moment, and we believe that this factor is of the utmost importance, not only in the matter of cause but also in prognosis and management. Its universal recognition and correct valuation by the profession is, I believe, of the utmost importance. I have not been able to show that these children are more liable to infectious diseases; nor, except in very rare instances, could their weakness and ill health be traced to any one illness. It has been my experience that the child who is naturally vigorous and lives in ordinarily hygienic surroundings regains rapidly his usual state of vigor following any temporarily depressing influence, such as acute disease; and I believe that such diseases cannot be said to be a marked factor in the establishment of the enteroptotic habit. I believe, however, that long-continued bad hygiene or chronic diseases affecting the nutrition may be determining factors in early life in its establishment, but this, in my experience, has been exceptional. As a result of failure to recognize the hereditary fundamental constitutional tendencies, efforts have not been uncommonly directed to the relief of local symptoms as if they existed independently. I believe also that bad hygiene has a marked influence on inherited frailness and, conversely, that the best of hygiene may considerably modify its tendencies.

If one questions as to the extent of the prolapse itself during childhood, one must admit that but few exact observations have been made along this line. Butler, of Chicago, in a carefully prepared and excellent paper, read in the Section on Diseases of Children, has examined some 155 children. I have, myself, entered enough into the study to show how different the mechanical conditions are and how little one may depend on the signs on which one is accustomed to rely in the adult. Butler has shown, however, that the fundamental characteristics of the enteroptotic habit are present in childhood—namely, the lack of nutrition and vigor—and that there is at least some tendency to the peculiar adult configuration of form and a displacement of the organs to be found at or near puberty. He has found that prolapse of stomach and kidneys in early infancy should not be looked on as signs of the enteroptotic habit. No extensive *x*-ray examinations have been made to definitely determine the position of stomach and intestines in infancy and childhood.

What shall we call the congenital factor above mentioned? Noble would frankly call it a degeneration and would class it broadly with those other degenerations well recognized and of greater degree. He is not alone in this opinion. Martin believes that it is an arrest at some point in development from embryo or a reversion to a lower type. Because of the differences of opinion as to what is meant by the term degeneration and for other reasons, I would prefer at present to merely define it in the terms of the phenomena which are exhibited; namely, a tendency to backwardness in physical development, to poor nutrition and an unstable nervous state.

Lack of nutrition and flabbiness of tissues may be said to be the chief underlying mechanical causes of visceral displacement. Later in life child-bearing becomes a factor to be recognized, since it strains the already weak anterior abdominal wall and tends to increase the general laxness of the tissues. In this connection I may speak of the so-called acquired type of enteroptosis (Fig. 7). The woman, however vigorous and well developed during childhood and girlhood, may, through hard work, child-bearing, or other untoward influences, bring about a laxness of tissues and bulging of her abdominal walls; and in such a woman it is not infrequent to find a palpable kidney and other organs downwardly displaced. It must be emphasized, however, that the degree of prolapse of the abdominal viscera in these cases is of much less degree than that found in true enteroptosis. It is common, however, to see the conditions mixed. In the already enteroptotic woman, if the cause above mentioned is added the prolapse is still further increased.

In a physical study of these four or five hundred women I have met women of almost every age, state of nutrition, habit, attitude and body configuration. From the viewpoint of enteroptosis it has served to bring out the fact that enteroptotic women form by no means a sharply defined group by themselves. On the contrary, there is nothing approaching a line of distinction. On rare occasions the physician sees a woman who has an almost ideal physique.[12] Such a woman has a figure closely conforming to the ideal figure of Greek art—a deep, large thorax, a voluminous upper abdomen, tissues firm, muscles well developed and sufficient adipose tissue to round out her angles (Figs. 8, 9, 10). With this ideal at one end of the scale and the markedly enteroptotic woman at the other, one meets all gradations. The women that are commonly called enteroptotic are those in which the anomalies are well developed. As they advance in life many of them gain weight and in this state the fundamental defects in their constitution may be easily overlooked. An inspection of the thorax gives one the quickest hint as to the patient's true constitutional makeup. I have not been able to learn by *x*-ray evidence the effect of a gain in weight on the visceral prolapse but I believe it to be a considerable one for the better.

I have purposely left much to be considered by others. My idea here has been to give, if I could, a broad estimate of the subject in general, based largely on my individual study. Much remains to be done. The profession is slowly establishing a substantial basis for the more practical and useful problems that are to be met and dealt with. A clear recognition of the defects that these women have to contend with—their tendencies, the real nature of their symptoms and, above all, the early history of their lives—I hope, will lead to an intelligent management during childhood and more intelligently directed efforts later on.

Wonderly Building.

---

[12] It must be understood that a large percentage of the women who come to the gynecologist are of less than the average vigor and that it is probable that a large number of ideal or nearly ideal women could be found in any community.

SURGICAL ASPECTS OF ENTEROPTOSIS *

A. J. OCHSNER, M.D., LL.D
Surgeon-in-Chief of Augustana Hospital and St. Mary's Hospital; Professor of Clinical Surgery in the Medical Department of the University of Illinois, Chicago
CHICAGO

In order to obtain a useful and practical view of the surgical aspects of enteroptosis it seems important to refer at the outset to the causation and development and incidentally to prophylaxis.

Since enteroptosis as a definite condition was brought forcibly to the attention of clinicians by Glénard a quarter of a century ago, many careful observers have been convinced of the fact that patients who suffer from marked enteroptosis are as a rule congenitally deficient anatomically and that their deficiencies are constantly exaggerated during childhood and more especially in females during the increased physical and physiologic burdens of childbearing.

Four years ago, R. R. Smith[1] directed our attention to enteroptosis with special reference to body form; and recently Reynolds and Lovett have shown that the condition occurs in persons of peculiar postures whose bodies are not normally balanced when they are in the erect position. Round-shouldered patients with hollow backs, large pelves and small chests are especially well formed for the development of enteroptosis. This naturally suggests an important field for prophylaxis through careful orthopedic treatment, especially of young women and children. Reed and Robinson[2] have observed gastroptosis in 37.6 per cent. of the tuberculous patients they had an opportunity to examine in a sanitarium.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

[1] Smith, R. R.: Tr. Am. Gynec. Soc., Philadelphia, 1906.

[2] Reed, Boardman, Robinson and Neal, Frank: South. California Pract., November, 1908.

Personally I have observed a very large number of children under the age of 12 who came under my care for the treatment of hernia produced from excessive intra-abdominal pressure in whom there was a marked degree of enteroptosis with diastasis of the recti muscles and pendulous abdomen.

The abnormal intra-abdominal pressure in these cases was due to one or more of the following causes: (a) digestive disturbances with gaseous distention of the stomach and intestines; (b) constipation; (c) phimosis with obstruction of the passage of urine; (d) chronic coughs complicating one or the other of the above conditions; (e) chronic appendicitis; (f) severe straining during the act of crying usually caused by pain due to one or more of the above conditions.

In these cases I have found that by removing the cause of the increased intra-abdominal pressure not only was it possible to cure the hernia without operation but the enteroptosis improved greatly in all cases and was entirely cured in many.

The intestines, no longer being overdistended, were able to contract to a normal size; the reduction in the amount of intestinal contents undoubtedly permitted the elongated mesentery to contract into its normal length; and the muscles of the abdominal wall were able to shorten and thicken and to hold the abdominal contents in their normal relation above instead of in front of the pelvis, especially when the treatment was instituted early enough to permit the diastasis of the recti muscles to disappear.

Aside from relieving the abnormal intra-abdominal pressure in these children, more especially by the regulation of time of feeding and quality of food and by this and other means overcoming constipation, their habits of rest were regulated so that they retired to their beds at 6. The foot of the bed was elevated so as to make an angle of 15 to 30 degrees between the planes of the bed and the floor. This virtually placed the patient during the hours of rest in the Trendelenburg position in order to force the abdominal viscera to gravitate toward the diaphragm, which enabled all of the supporting structures to recover from the strain to which they had been exposed by the abnormal intra-abdominal pressure.

The obstetrician has accepted his share of the prophylaxis and the orthopedist is at the present time eagerly searching out his share in this work. We must now ask the pediatrician and the dietitian to take their respective shares in reducing the number of these cases; then, after the gynecologist has disposed of those belonging to his especial field, the remaining cases must be viewed by the surgeon in a most critical way from several standpoints.

In the first place, in a vast majority of patients with enteroptosis this condition does not materially affect the disease from which the patient is suffering; and, in the second place, in a vast majority of patients in whom the presence of enteroptosis does affect or cause the disease from which they suffer, surgical treatment either fails altogether in producing relief or it introduces other conditions incidentally which in themselves cause abnormal conditions worse than those from which relief is sought.

Joseph Blake gives as an indication for operation the following conditions: First, it must be determined that the patient's suffering is due to enteroptosis; second, it must be clear that the condition cannot be relieved without surgical interference; and third, it must be reasonably certain that the condition can actually be relieved by a surgical operation.

It seems that enteroptosis is the cause only in cases in which its presence produces obstruction. The obstruction may be caused simply by a more or less marked angulation, or even by torsion, especially if the enteroptosis is complicated with adhesions. A stomach whose ability to empty itself in the normal period of time has not been impaired should never be operated on for enteroptosis. If the latter condition causes obstruction of the pylorus surgical treatment should be considered; consequently the presence of gastroptosis in itself should never be considered an indication for surgical treatment. The same is true of nephroptosis. In the examination of a large number of foreign-born working women I was able to confirm the statement of Pavlick that 75 per cent. of the women of this class who have repeatedly borne children have right-sided nephroptosis; but I have also found that this condition is of no importance unless it gives rise to obstruction of the ureter and overdistention of the pelvis, a condition which is usually due to an abnormal arrangement of the bloodvessels of the kidney. In most cases it is possible to demonstrate the acute bending of the ureter over the abnormally placed vessel. But the number of these cases is very small in comparison with the number of cases of nephroptosis.

There is also a small class of patients in whom the nephroptosis interferes with the circulation of the kidney giving rise to albuminuria. In these cases nephrorrhaphy is also indicated.

Enteroptosis of the small intestines is still less important unless complicated with adhesions which may be simply a complication or in other cases these adhesions may be partly responsible for the enteroptosis.

The splenic and hepatic flexures of the colon are the only portions of that organ that are rarely involved in enteroptosis; the cecum, transverse and descending colon and the sigmoid flexure may be found at any level of the abdominal cavity. This is probably due in most cases to faulty fetal development, as shown by Babcock and others. Whenever the malposition of this organ is sufficient to cause so much obstruction to the passage of feces as to impair the patient's health because of the resultant malnutrition or auto-intoxication, the operation introduced by Mr. Lane for the removal of the offending portion of the colon is undoubtedly the most rational form of treatment, but in this country this operation is but rarely indicated, primarily because the habits of Americans preclude the conditions of fecal accumulation encountered in so many patients of the lower classes in some European cities. In the greatly exaggerated conditions encountered in Hirschsprung's disease, excision is of course invariably indicated, preferably by the simple method described by Judd.[3]

In our clinic we find ptosis of the transverse colon in more than 25 per cent. of patients operated on for other conditions in whom this condition has no relation to the disease of the patient and is undoubtedly either congenital or due to abnormal intra-abdominal pressure during childhood.

In case of obstruction to the ureter due to nephroptosis nephrorrhaphy is indicated by one or the other of several efficient methods which have been thoroughly tried. In gastroptosis, causing pyloric obstruction the operation for supporting the stomach introduced by Beyea[4] is indicated, because, while it overcomes the mechanical difficulty in the case, it does not fix the organ. All operations which serve to fix intra-abdominal organs for the relief of enteroptosis are bad because they introduce a condition resulting in much more harm than is done by the enteroptosis itself. The intra-abdominal organs are normally in a floating condition which insures comfort to the patient and protects these organs against jarring, hence the necessity of maintaining this condition.

---

[3] Judd, E. S.: Journal-Lancet, Jan. 1, 1909, St. Paul, Minn.

The relief of the condition of ptosis of the pelvic organs has been thoroughly studied and described by those interested, especially in the field of gynecology.

Here also the fixation of organs has been wisely condemned. One condition should be mentioned here because it is constantly encountered both by the surgeon and by the gynecologist, I refer to the pendulous abdomen which Quincke[5] discussed fully in connection with all forms of enteroptosis. When present in connection with umbilical hernia it should be relieved by a very extensive sliding of transverse flaps introduced by W. J. Mayo for the treatment of umbilical hernia. When no umbilical hernia is present, then we should employ the method of overcoming the diastasis of the recti muscles introduced by Clarence Webster, consisting in laying bare the rectus abdominus muscle on either side of a median incision by laying open the fascia and then suturing all of the layers successively securing union between the internal edges of the recti muscles. In all cases, no matter what the condition may be, for which the patient has been subjected to an abdominal section in which enteroptosis and diastasis of the recti muscles are present, this operation is indicated.

The important point about this operation comes from the fact that it corrects the vertical relation of the intra-abdominal viscera to the pelvis, placing them above instead of in front of the pelvis.

We still have to account for a ptosis of liver, gallbladder, urinary bladder and spleen.

In a moderate degree of ptosis of the liver relief can be obtained by making a longitudinal incision parallel with the right rectus abdominis muscle and splitting this muscle longitudinally for a distance of 5 cm. downward from the last rib and then suturing the gall-bladder to the edge of the wound, the sutures grasping peritoneum and transversalis fascia. The gall-bladder should be opened and drained for two or three weeks, which will usually result in a marked decrease in the size of the liver.

The same operation gives relief in patients suffering from ptosis of the gall-bladder, which is frequently accompanied with an accumulation of thick, viscid sandy bile or gall-stones in the gall-bladder with more or less obstruction of the cystic duct. These patients should cease wearing corsets and should wear their skirts suspended from their shoulders in order to remove the abdominal pressure from these sources.

In extreme cases of ptosis of the liver the anterior surface should be roughened by friction with dry gauze and a number of chromic catgut sutures should be used to unite the anterior surface of the liver with the parietal peritoneum. The fixation thus obtained is not nearly so satisfactory as the support obtained by the cholecystorrhaphy in the milder cases.

In ptosis of the spleen operation is indicated only when there is obstruction due to extreme mobility of the organ suspended by a long pedicle. A pocket may be formed of the peritoneum into which the loose spleen is fastened. I have removed the spleen in such cases, but the experience in either of these operations is too small to be valuable.

In all cases of enteroptosis, dietetic and hygienic measures must be employed in the after-treatment in order to eliminate as far as possible, abnormal intra-abdominal pressure from every source, but especially from gaseous distention and constipation.

ENTEROPTOSIS—THE PHYSICIAN'S VIEWPOINT *

J. H. MUSSER, M.D.
PHILADELPHIA

It is possible that there has been an exaggeration of the importance of congenital gastroenteroptosis as a factor in the production of symptoms. Investigations by modern methods, as the *x*-ray, *show that this ptosis* is of frequent occurrence when not suspected. The individual is without symptoms unless some complication, as an inflammatory lesion, arises. Independently of such *complication, if symptoms are present, they* can be demonstrated to be due to other factors. These factors of ill health in the large proportion of cases are the result of antagonistic environmental conditions, which in an individual handicapped by congenital insufficiencies, are not met by healthful reactions of the organism. In consequence the organism is overwhelmed. The environmental conditions are those which make for effeminacy in our life. Modern types of living, overstimulation of the nervous system by all forms of excitement, improper diet, foolish amusements, excesses and irregularities of all kinds are the factors productive of symptoms in gastroenteroptosis. This view seems to be supported by the fact that the laboring classes are not often victims of that symptom-complex of general and visceral neuroses, which is so common in the leisure classes. It may also be said that the victims of the neuroses with enteroptosis are usually members of a family in a period of involution. They are luckless survivors of a family about to become extinct. They may have stigmata of degeneracy and are almost sure to have the type of thorax known as the phthisical or paralytic. If one traces the morphology of antecedent generations, it can be seen that with each generation there is structural evidences of physical decline.

Moreover, one is supported by the clinical evidence and by the results of treatment in the view that the enteroptosis is only part of a general condition, and is not of itself sufficient to give rise to symptoms. Through the clinical evidence we learn that the morphologic condition and the clinical expression of any gastroenteric insufficiency is seen in the statement that from childhood there has been poor health and that abdominal symptoms always obtain. Thus, in one hundred cases of gastroenteroptosis taken without selection from more than six hundred cases, and not divided into congenital and acquired, the evidence is strong that 37 per cent. had always been in poor health, while 27 per cent. had presented symptoms from a time when the strain of evolution was a factor added to the congenital condition.

---

[4] Beyea, Henry D.: Am. Med., Oct. 8, 1904.
[5] Quincke, H.: Therap. d. Gegenw., 1905, xlvi, 10.

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

Unfortunately, the history does not record the general conformation of the individual, which enables one to predict ptosis, and which prediction is almost always confirmed by exhaustive examination.

The results of the treatment or management of such cases lend further support to my view. I have in mind many individuals with gastroenteroptosis in childhood who, notwithstanding that they often were of involution family groups, escaped the many perilous ills familiar to us as belonging to this period, because of favorable environmental conditions. They had the advantage of a robust sensible home life and of conscientious, wise mothers. They had every environmental agency that makes for health, a rational education and normal amusements. Some of the girls have grown under my eye to be healthy mothers of families, and the boys to be wise dispensers of their strength, which has made them normal members of a community, though not overbearing because of their powers as athletes.

Finally, I may state that I have made metabolic analyses in ten of these cases of enteroptosis without finding any important evidence of malnutrition or perverted nutrition or of a toxemia which could fairly be attributed to an uncomplicated enteroptosis. Furthermore, I can state, although with some qualification, that whatever indications of toxemia I have found in such cases as indicanuria or alteration in the proportion of the sulphates, or of changes in the feces indicating fermentation, etc., such modifications can be ascribed by the neurosis which accompanies the congenital insufficiencies.

In short, with such a congenital morphologic condition, there is also a state of the nervous system attended by visceral hyperesthesia which if not carefully guarded against brings with it a state of introspection, the ensemble of which is typical of the neurosis of enteroptosis. Any attempt, therefore, to relieve such conditions must be directed not to any one part of the organism but to the organism as a whole. Any attempt which will render one part of the organism more hyperesthetic, as will operative procedures, will increase the neurosis, and delay recovery temporarily or even permanently.

If, then, we must not allow ourselves to consider enteroptosis as a single factor, what can be done to relieve any symptoms to which it apparently gives rise? I take it that we agree that such symptoms are the result of secretory neuroses, gastric and intestinal, and motor insufficiency with secondary toxemia. Let us inquire into the defenses and adaptive powers which the organism possesses, provided the individual listens to the responses of the organism as seen in the reactions it manifests. Unfortunately we are brought face to face with the problem long after the organism has become oblivious of these responses, when the reactions are negative features. Indeed it is the ever-watchful eye of the mother in the early periods of the child's life that usually detects them, and if bridge and teas and other diversions of our vaunted modern life do not distract her from her duties, she controls the reactions, represses them when in excess, stimulates them when deficient and carefully guides the child into normal adolescence and healthy manhood or womanhood.

The defenses the organism possesses against such insufficiencies are only those which conserve health. If watched for it can readily be seen that such an individual has limitations which must not be disregarded. The so-called bilious attacks, the attacks of exhaustion, of headache, of nervousness, the various neurasthenic and hysteric phenomena are expressions of fatigue of an organism which cannot mark time. The defenses of the organism are rest and temporary abstinence or moderation in all things. If these efforts of the organism are not frustrated by an ambition along the social or educational lines these defenses will be rationally encouraged. They will not be thwarted by the stimulants used to goad tired Nature and by narcotics, both of which it is true are likewise more in vogue later in life, establishing before long a vicious circle and reducing the organism to a state in which its existence depends on artificial conditions. In short, we must combat not only the congenital insufficiency, but also the fatigue neurosis which attends it.

It is not only by the defenses of rest (physical, mental and emotional), that we see the organism meet the insufficiency of its powers, but by adaptation also. This is seen in the development of a tolerance to any intoxication (an exaggerated factor, however, I believe), in the occurrence of hypertrophies to overcome obstructive lesions, and of secretory balance to mitigate any aberration in that line. If the organism has half a chance the chemical correlations and internal secretions will take care of the insufficiencies.

It will be asked if the organism has even a modicum of defense and adaptation, why it is necessary to invoke the aid of the physician. The answer is that the defensive and adaptive powers have not been heeded and that every excitation or irritability which arises from weakness of the organism invites excesses beyond the power of the organism. The individual does not live down to his strength but spends both income and capital to the verge of bankruptcy.

Inasmuch as failures of defense occur, as seen in women after nervous strain or after childbirth with its accompanying anatomic and physiologic changes, and in growing males after misguided athletic endeavors, or in still more vicious effeminacy and stimulation of the adolescent period, what can be done to aid the organism? Aid it needs, and in any attempt to assist we must realize that not only is the organism handicapped, but the symptom-complex indicates that the organism as a whole, its vital powers and environmental conditions, play a large, if not the most important part in the production of symptoms. It must be realized that it is not a disease but a condition which confronts us. It is one thing to manage a condition and another to treat a disease. The former requires all the resources we may have at our command along lines of physiologic therapeutics; the latter requires us safely to conduct the organism to health by methods of antagonism, neutralization, counteraction, destruction, direction and assistance, which are physiologic and pathologic. Above all, the former requires the wholesome tonic influence of a robust personality in the physician and other individuals associated with the patient. It is not for me to present a homily on hygiene. I may be permitted, however, to urge that the general principles and methods of hygiene should be invoked and applied in directions specifically suitable to the individual patient; that to this must be added an indirect therapy based on a correct estimate of the functional value of each organ or system. That it is necessary to treat the eyes, the muscular system, correct postural defects, and all the organs requiring it, goes without saying.

It is evident that there is no specific, and it is likewise evident that no insults to the nervous system are to be permitted by injudicious surgical procedures. A little relief can often be obtained perhaps psychically, but also physically by the use of a bandage. A notable result by such treatment was seen in some of the one hundred cases previously mentioned. A bandage was ordered for nineteen patients in whom the history indicated a congenital origin; five were much relieved, ten a little relieved and four experienced no relief. About 25 per cent. thought it worth while to wear a bandage. Drugs may be employed, as iron, nux vomica, physostigmin, and also laxatives, of which the most effective is rhubarb. Now and then sedatives of mild form, as the bromids, sumbul and valerian, may be judiciously employed.

We must pause a moment to consider the congenital visceroptosis, on which acquired physical conditions are engrafted, which lead to obstructive symptoms, chronic constipation and its secondary disorders. A different condition confronts us. Hence the judicious surgeon or internist must estimate the relative effect on the organism of operative procedure, and of a continuance of the abnormal conditions. I am free to admit that the presence of inflammatory adhesions, of undue dilatation or of obstruction, demands the intervention of the surgeon.

Here also a word may be said of the patients with visceroptosis who cannot have the opportunities of hygienic treatment which I have spoken of. Such are unable to carry on their usual avocations and are practically helpless; for them a chance must be taken, and it may be wise to resort to surgical procedure.

The acquired visceroptoses are most amenable to surgical treatment. If judicious abdominal support, the repair of losses of external support and indirect and hygienic therapeutics are not of avail, resort to surgical procedure is necessary.

What I have said regarding operative procedure in congenital ptoses may have to be qualified with the turn of a night. The argument that the enteroptosis should not be treated by surgical measures because other congenital states exist, and notably those of the nervous system, might be applied to other congenital conditions. It might be said for similar reasons that one should not operate on hare lip or cleft palate. If we could recognize congenital ptoses early and before the neuroses develop we might be able to forestall the ill effects of insufficiencies. Who knows but that in the near future such early recognition will be possible, and early remedial surgical relief applied?

1927 Chestnut Street.

THE *X*-RAY DIAGNOSIS OF ENTEROPTOSIS *

EDWARD HOLMAN SKINNER, M.D.
KANSAS CITY, MO.

The *x*-ray diagnosis of enteroptosis is at once a simple procedure with definite conclusiveness. The *x*-ray furnishes a method to determine with exactness the position of the large and small bowel within the abdominal cavity.

This examination does not demand an *x*-ray equipment above the average. A 12-inch coil, with electrolytic interrupter and a tube capable of standing a primary current of 20 amperes for thirty seconds will suffice.

On account of the comparatively equal densities of the abdominal contents, it is necessary to render the colon transparent or opaque in outline. The following means may be used to adapt the colon to Roentgen examination:

1. Inflation with air, per rectum. This method is not satisfactory because the air-pressure within the colon is unequal, and, further, does not give an exact record of the lumen of the colon on the fluoroscopic screen or negative.

2. The distention of the colon with opaque emulsions, injected per rectum. Distention by injected emulsions produces a colonic distention with uniform filling pressure when properly conducted.

The technic of the rectal injection is as follows: The patient, having had an intestinal cleansing previously, is placed at ease on the left side, with hips elevated. There should be complete relaxation of the abdominal musculature. A soft rubber tube, about one-fourth inch lumen, is inserted, and the emulsion allowed to flow gently, as the first portion of the injecta may produce colonic contractions that would foil our purpose. The pressure of the flow should be about 8 to 20 inches. The injection should require about thirty minutes for 2 quarts of emulsion. The examination within the next hour will disclose the filling of the large intestine to the ileocecal valve. The average capacity of the adult rectal ampulla is 1 pint, and of the large bowel 3 quarts.

3. Distention of the colon with opaque substances ingested with food. By this method the residue of a bismuth meal is radiographed in the colon, sufficient time (usually sixteen to twenty-four hours) having elapsed since its ingestion to insure its presence in the colon.

Opaque substances of radiographic usefulness include, first, the bismuth salts—subnitrate, carbonate, subcarbonate and oxychlorid. Of these, the oxychlorid is best, not having any deleterious effects and not undergoing chemical change. The subnitrate has been discarded because of some unfavorable reports and the care necessary in its selection commercially. Second, the iron preparations, including manganate of iron.

For ingestion by mouth, these opaque substances must be held in suspension by a gruel, or porridge of rice, milk and bread, meal of peas, oatmeal, etc. I myself use about 2 pints of porridge, into which one or two ounces of bismuth oxychlorid is thoroughly mixed, flavored with raspberry syrup or grape-juice.

For an injection per rectum, I use an emulsion of 2 ounces of bismuth oxychlorid in 32 ounces of milk, with 4 drams of acacia to sustain the bismuth, or an emulsion of olive oil and bismuth oxychlorid. It is worse than useless to draw diagnostic conclusions from the injection of simple bismuth in water.

The *x*-ray diagnosis may be made by (1), fluoroscope, or (2), radiograph.

1. The fluoroscope examination should be conducted in a room of absolute darkness, on a good protected fluoroscopic screen of a size (11 by 14 or 16 by 20 inches) sufficient to cover the entire field of inspection. The fluoroscopic outlines of the opaque colon may then be charted on the glass covering to the fluoroscopic screen and this transferred to paper for a permanent record. If the physician or Roentgenologist is provided with fluoroscopic apparatus that protects the patient and operator, this examination may be conducted expeditiously and without the tedious detail of the radiographic exposure. But without good fluoroscopic apparatus, one is confined to a radiographic technic.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

2. The radiographic examination should be made with a plate not less than 11 by 14 inches in size, usually 14 by 17. The plate should be placed with the emulsion surface against the abdomen, the umbilicus having been marked with a copper cent, attached with adhesive, and the tube opposite the fourth lumbar vertebra and at a distance of 20 to 22 inches from the plate. The use of the usual *x*-ray plate will usually give sufficient detail with an exposure of ten to thirty seconds, with a primary current of 20 amperes, through a 12-inch coil and a tube of medium penetration. The topographic outlines of the colon alone being sought, it is quite satisfactory to shorten the exposure and increase the contrast by means of an intensifying screen, especially the new Gehler-Folie or Sinegram screen, which produce negatives relatively free from small flecks.

The interpretation of the radiographic and fluoroscopic shadows is greatly enhanced by study and experience. Before examining by the fluoroscope, the observers should remain in absolute darknesss for ten minutes to secure an ocular accommodation. This is especially advisable to one unfamiliar with fluoroscopic shadows.

The landmarks of our *x*-ray picture are the umbilicus and ensiform cartilage, marked by pieces of metal, and the wings of the ilium. The shadow of the cecum should be within the wing of the right ilium. We may then trace the colon to the hepatic flexure. In a well-filled colon we may see the hepatic angle completely filled with the emulsion, but sometimes the apex of the angle will show some transparency produced by retained air. The splenic flexure is higher than the hepatic, and also shows a sharper angle with air at the apex. The shadow of the transverse colon should be noted in its relation to the umbilicus and its movability noted by direct abdominal manipulation. To determine the movability of the colon in radiographs, it is necessary to take two exposures; one with the patient standing, the second with the patient in the Trendelenburg or prone posture. The study of the movability of the colon and possible adhesions thereto is best accomplished by the fluoroscope.

The hepatic and splenic flexures of the colon may appear sharply angled with possible kinks. This is usually faulty interpretation, as what appears to be an angle is really a curve, the upper portion of the ascending colon being overshadowed by the first part of the transverse; likewise, the first portion of the descending colon may be overshadowed by the distal portion of the transverse colon. If there be a kink that obstructs, there is a damming up of the opaque emulsion on the side from which the emulsion was introduced.

To avoid errors in the estimation of the distance of the transverse colon above or below the umbilicus, it is necessary that the direction of the *x*-ray delivered from the *x*-ray tube strike the fluorescent screen or plate at a perpendicular, and at a point on the back opposite the umbilicus, about the fourth lumbar. In the study of a particular portion of the colon, where adhesions are suspected it is desirable to diaphragm down to the area on the fluorescent screen. This is not necessary in radiographs, as the entire colon may be studied at leisure, but without the advantage of continued observation under manipulation that the fluoroscope affords.

CONCLUSIONS

Having rendered the lumen of the colon opaque, it is possible to record exactly, either by fluoroscope or radiograph, the position of the colon in its relation to the umbilicus and bony skeleton. The fluoroscope will give diagnostic information beyond the radiograph, in that changes in position of the colon, due to manipulations and adhesions, may be studied.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SKINNER, MUSSER, OCHSNER AND SMITH, FORMING A SYMPOSIUM ON ENTEROPTOSIS

Dr. Max Einhorn, New York: I think it was in 1895 or 1896 that my paper on "Movable Kidney and its Treatment," was published in the *Medical Record*. At that time most movable kidneys that were recognized, were operated on, and I think I stood almost alone in the opinion that movable kidneys should not be operated on. It is not movable kidney alone that gives the trouble, but there is usually associated a movable stomach, or liver, or other organ. Such conditions are found more often in women than in men. Whether or not it is congenital is difficult to state. I am of the opinion that in some cases there is congenitally a tendency to develop such anomalies. That such conditions exist in normally developed children, who later develop affections that lead to enteroptosis, we have ample proof in the fact that proper treatment brings permanent cure. If the condition existed from birth this would not be so. Another point is that a strict diet is just the opposite to what is required. In all these patients, unless there is a strong contraindication, it is important to make them eat. The patient may tell you that he cannot eat eggs. If you will allow this to guide you, you will never succeed. Tell your patient to eat a little at a time, and that in two or three weeks he will find he can eat everything, and that is the only way to cure such patients.

I do not think that enteroptosis as such gives rise to great disturbance of the motility of the stomach. If you find food in the stomach in the morning with a prolapsed condition, the prolapse is not the cause of the stomach not being emptied. There may be some other condition associated. I would say that this is not a phenomenon of enteroptosis.

Dr. R. C. Coffey, Portland, Ore.: It is pleasant to see an afternoon devoted to this subject in a surgical section of the American Medical Association inasmuch as many of the leading surgeons of our country have absolutely opposed surgical treatment of these cases. The first patient whom I treated surgically was one in whom I could find nothing else wrong. The patient had gone from the condition of a strong, healthy woman to a condition of severe vomiting, just as if she had an obstructive ulcer at the pylorus. I had heard of nothing at that time that had been done on the subject. I told the patient's husband what I would like to do in the case and he consented. I sutured the omentum to the abdominal wall.

The patient fully recovered and weighs 160 pounds; she weighed 80 at the time of the operation. Since then I have operated on 22 other patients for ptosis of the stomach. I think Dr. Clark has given us one of the best pieces of advice to-day: not to operate for the pathologic condition as it appears from the clinical examination, but to operate for symptoms alone. I remember that Dr. Clark, some years ago, in a paper advocated this operation in certain cases in which he had incidentally found the stomach low down while doing other abdominal operations. I am glad that he has changed his opinion. We never should operate on the stomach simply because it is low. In but two cases have I operated in which the patient was not an absolute invalid. That is the rule that we should adopt. In only three cases have I operated for general ptosis. Most of my operations have been for prolapse of the stomach alone. Four patients had displaced liver and one or two had displaced kidneys. There were two cases of general ptosis; operation was done in two stages. In one case the patient had been an invalid for five years. The stomach was also prolapsed and the uterus retroverted, as is common in these cases. I anchored the stomach, liver and kidneys, and suspended the uterus at one operation. I found the congenitally narrowed condition which had been mentioned and on attempting to close the abdomen it seemed too small. I had then turned the fascia of the rectus in from above, leaving only the posterior portion of the fascia, thus extending the abdomen at least two inches. Six weeks later, I made two incisions, one on each side midway between the umbilicus and anterior superior spine of the ilium, and parallel to the fibers of the fascia of the external oblique. The fascia was overlapped for two inches on each side, as shown in article in *Surgery, Gynecology and Obstetrics*, thus changing the entire contour of the patient's abdomen. The patient is doing her own work and feels absolutely well. In two other cases I did the same thing.

Dr. C. F. P. Korssell, Chicago: I emphatically believe in the surgical treatment of enteroptosis. I have had some little experience and endorse the view of intra-abdominal pressure being a causative factor of great importance. In seventy-four women and two men operated on for enteroptosis by a new method, sixty-three had previous diagnosis and were deliberately operated on for its relief. Eighteen of them had previously been operated on for gynecological troubles without relief. My work has been in aggravated cases, in patients prostrated, useless, and with life a burden. They have been mostly those complicated with pelvic troubles and in quite a large percentage the small intestines were principally involved, being prolapsed into the lower pelvis below the promontory of the sacrum and bent back around its acute angle, usually with the uterus pressed down, retroverted and the fundus resting on the intestines, compressing them against the sacrum. The operation is done through a transverse or the usual incision, above the symphysis. After raising the intestines and emptying the pelvis completely of intestines, packing them out of the way, an incision is made in the posterior peritoneum about one inch long just to the right of the rectum, either transversely or longitudinally; then grasping the cul-de-sac of Douglas, or, in some cases, the neck of the uterus, well down with a tenaculum forceps and approximating it posteriorly to the sacrum just below the promontory and stitching it into the cut in peritoneum with chromicized catgut or silk, a firm anchorage is secured for the uterus posteriorly and permanent suspension. The same procedure is carried out to the left of the rectum with or without incising the peritoneum. The sutures are continued on each side from these central points of suspension for sewing the broad ligaments on the same level to the sacral peritoneum, a half-inch below the promontory, until the true pelvis is entirely closed up by a diaphragm of double layers of peritoneum, which experience has shown to be of ample strength to keep the abdominal organs out of the pelvis.

I have deferred reporting this work in the hope of having some of these patients come through pregnancy, but have so far waited in vain. However, I do not believe the condition produced would materially interfere or complicate natural labor, especially if one were not in too great haste. Such patients should have ample dilatation of the cervix before resorting to the use of forceps.

Dr. J. H. Carstens, Detroit: Prevention is the great desideratum. The illustrations of Dr. Smith show the peculiar shape of the body, which indicates the tendency toward general abdominal ptosis. This being the case, we should prevent the latter by systematic development of the body by physical exercise and not too much school work. Why do we have so much ptosis and neurasthenia? Because many of the girls at this age are ambitious; they want to learn and to become stenographers, teachers or members of some other profession, and still they haven't the right kind of brain; they learn with difficulty; they must study hard, until late at night. To make matters worse, perhaps some good aunt pays for a music teacher and they also play on the piano during this stage of development, and then when they are 18 or 19 years old graduate from the high or normal school physical wrecks, with a certain amount of mental development and with a sour and cross temper. We must prevent this condition. Such a girl must stop her education for a few years; she can make it up easily afterward, if necessary. Such a girl must be sent to the country. Let her jump over the fences, chase the cows, feed the chickens, fall in the river, swim, row a boat; in other words, be a regular "tom-boy." With plain nourishing food, in the course of a few years she will develop into a strong, healthy woman with a virile body, withe not so much learning, but with a sweet temper.

Dr. A. W. Crane, Kalamazoo: It seems to me that the usefulness of the x-ray examination of the stomach and intestines by surgeons is greatly circumscribed. It is mentioned but little in the books, in journals and in works on the x-ray itself. It does not seem to be described in the books on general surgery and medicine. To my mind the x-ray examination of the stomach and intestines often furnishes more complete information than experimental operation. A surgeon may not be able to tell whether an ulcer of the stomach is present or not, even though he has the stomach in his hand, but he may be able to tell from the x-ray examination that such exists. It seems to me that except in emergency cases, no surgery of the stomach or intestines should be done until x-ray examination had been made.

ARTHRITIS OF GASTRO-INTESTINAL ORIGIN, ITS DIAGNOSIS AND TREATMENT [*]

H. W. MARSHALL, M.D.
BOSTON

An obscure relationship between disorders of the digestive tract and joint affections has long been recognized by clinicians, and in the last decade some of these relations have become better understood. It is now known that severe cases of arthritis may occasionally be completely relieved by preventing absorption of intestinal contents in the large intestine. This may be accomplished by intestinal lavage, purging, regulation of diet, and by operations on the colon that cause fecal material to be discharged through artificial openings, thus putting the lower portion of the intestine entirely out of function.

Various intestinal affections may influence joints, and it is interesting to observe that typhoid fever and bacillary dysentery both are occasionally accompanied by joint lesions, while in appendicitis arthritic complications are too infrequent to seem more than mere coincidences. The few scattering cases of arthritis that occur with rarer diseases of the alimentary tract will be disregarded in this paper.

Keen[1] states that there were 84 cases of arthritis among 1,700 cases of typhoid fever collected by him, and Garrod[2] estimates that 3 or 4 per cent. of bacillary dysentery show joint complications. In the very common malady, appendicitis, Sutherland[3] has been able to collect only 6 cases in which there have been pronounced articular pains, and these seem to be too few to indicate any real relationship. Garrod[2] says that he has been unable to obtain any reliable instances of joint disease occurring with amebic dysentery, but W. E. Musgrave[4] records that chronic rheumatism both of the articular and muscular types is very frequently encountered, and in many instances seems to bear a very definite relation to amebiasis of the intestine. In comparison it should be remembered that gonorrheal arthritis occurs in 2 or 3 per cent. of patients suffering with the latter disease.

The joint lesions in typhoid fever and bacillary dysentery make their appearance after bacterial poisons have acted for several weeks. In practically all instances bacteria have not been found in the joint fluids.

---

In dysentery the arthritis usually subsides within a week or so, and affects the larger joints most commonly, especially the knees, in which there may be synovial effusion sometimes of extreme degree. Generally no permanent damage results.

Typhoid arthritis is sometimes polyarticular, but more commonly monarticular and it especially attacks the hip joint, in which spontaneous dislocation is a very frequent result from serous distention of the capsule due to the subacute synovitis.

CLINICAL DATA INDICATING THAT CONTENTS OF THE LARGE INTESTINE MAY ACT AS JOINT IRRITANTS

Attention will be given in what follows mainly to obscure intestinal toxemias originating in mild processes that are associated only with ordinary non-pathogenic intestinal bacteria.

Vague connections between intestinal disorders and joints have been recognized by many clinicians in the temporary improvements occurring in the latter following treatment of digestive irregularities, but these observations have been too indefinite to permit of reasonable deductions, and dependence therefore has to be placed on fortunate combinations of intestinal and arthritic symptoms that allow of no doubts as to their interpretation. Such cases are, however, rather rare. The following instance of fecal impaction accompanied by joint complications is the most convincing that can be cited at the present time:

Patient.—Married man of 50 years, physician, suffering with multiple arthritis; severe symptoms of several months' duration, preceded by two years of slow development of stiffness; arthritis involved spine, jaws, hands, knees and ankles, especially, and to less extent the other points. Nearly complete disability was present and joints exhibited periarticular swellings and limitation of motion, with edema of skin around affected parts, of moderate degree. Psoriasis was a very interesting feature, having a most extensive distribution over scalp, trunk and extremities and of duration longer than the joint lesions.

Personal History.—Patient was a healthy man previous to present illness; no infections or other etiologic factors discovered to account for insidious onset of joint trouble; tonsils removed without effect on joints; no digestive symptoms except occasional slight abdominal pains at night; patient always a hearty eater.

Examination.—This showed fecal mass in the cecum and tenderness at umbilicus. Bowels were moving once or twice daily with the use of sodium phosphate. Physical examination was otherwise unimportant.

Treatment.—Intestinal lavage, with physiologic saline enemas daily.

Result.—Enormous accumulation of fecal material evacuated at end of eight days. The edema about the joints and psoriasis began to subside slowly within two or three weeks, and the arthritis and skin lesions both steadily improved for several months and terminated in complete recovery that has remained permanent. Patient has continued treatment, taking fermented milk and keeping bowels well evacuated with cathartics and enemas, and has been able to resume active practice and play golf for the past year.

It seems reasonable to suppose in this case that substances were absorbed from the large fecal accumulation adherent to the intestinal walls and that these produced joint and skin lesions, as complete subsidence of two such severe conditions in skin and joints simultaneously after removal of the fecal mass scarcely permits of any other interpretation.

Having acquired this definite conception, it becomes possible to support this idea of intestinal toxemia by additional observations which of themselves seem less convincing.

Colostomies performed for various rectal conditions have been reported by different surgeons[5] to be associated occasionally with the cure of an arthritis which happened to be present coincidentally with the rectal disorder. Interpretation seems to be that while the surgical malady was being cured by allowing the intestine to remain at rest, simultaneously its absorptive function was also thrown into disuse, with the result that the joints were improved.

I have had charge of a patient suffering with rectal ulceration for which a colostomy was performed. In this case the artificial opening allowed a little fecal matter to get into the lower part of the bowel occasionally, and the patient was in the habit of irrigating the colon through the cecal opening himself; moreover, he could readily tell when such washings were needed by pains that began in his joints, and these subsided each time after irrigation, within a few days.

Purgation as a cure for arthritis from intestinal toxemia has been frequently employed at sanatoriums, and the marked improvements that often are related are to be explained on the assumption that they also diminish absorption by clearing the bowel quickly and thoroughly, and by increasing peristalsis. There seems to be no doubt that such improvements occur or that symptoms generally recur after the treatment ceases and accumulation again takes place.

ORIGIN OF INTESTINAL TOXINS

In typhoid fever and bacillary dysentery, toxins presumably are derived from special micro-organisms producing those diseases, but in the class of cases under discussion there have been no pathogenic bacteria recognized in the stools.

Theoretically three possibilities exist. 1. Some specific organism that produces the toxic substance, which has not yet been discovered, is present in the stools. 2. Ordinary non-pathogenic bacteria develop excessively, and the products of their activities exert a mild irritating effect on joint tissues from being in excess in the blood, similarly as excessive quantities of uric acid derivatives cause trouble with joints, although uric acid is a normal product of metabolism. 3. Defective digestion produces abnormal chemical products independently of bacterial action, and not of gouty nature, that are the cause of arthritis.

NON-PATHOGENIC INTESTINAL BACTERIA IN THEIR RELATIONSHIP TO JOINTS, AND CONDITIONS THAT ACCOMPANY THE PRODUCTION OF JOINT LESIONS

Examinations of stools of arthritic patients show no constant characteristics or any peculiarities that are not observed in patients who do not have arthritis. No bacteria have been discovered that are peculiar to this condition alone, yet hidden in this confusing state of affairs lies the cause of certain types of joint disease, shown by cures following removal of fecal impactions.

The relationship between intestinal toxins and joint lesions must depend on the following series of variable conditions, namely: variable formation of toxins, variable absorption of them through the intestinal walls, variable unknown processes in their passage through the liver into the general circulation, and diverse resistances of joint tissues.

---

5. Cave, Edward John: A Discussion on the Chronic Diseases Included in the Terms "Chronic Rheumatism," "Osteo-Arthritis," and "Rheumatic Gout," Brit. Med. Jour., Oct. 12, 1901, p. 1040. Wallis, Frederick Charles: The Causes and Treatment of Non-Malignant Stricture of the Rectum, Brit. Med. Jour., Oct. 6, 1900.

Production of toxins fluctuates with the quantity of nitrogenous food and according to the abundance of bacteria, and it may be diminished by changing the character and quantity of diet, by improving digestion and absorption of food in the small intestine, thus leaving less for bacterial decomposition, or by introduction of micro-organisms, as lactic acid bacteria, which inhibit the growth of putrefactive bacteria. The quantity of toxins absorbed depends on the amount formed, the rate of peristalsis, and also on inherent individual differences in powers of absorption. Resistance of joint tissues must also be considered a variable factor, as variability in vital resistance of all living tissues is one of the recognized facts of biology.

EXAMINATIONS OF STOOLS OF ARTHRITIC PATIENTS

Examinations of stools have been made a sufficient number of times from twenty-five patients to form an opinion regarding the presence of unusual species of bacteria, especially spore-forming anaerobes, and to allow comparison with non-arthritic individuals. Some patients were selected because their joint condition seemed to be of intestinal origin and others were chosen because the intestinal tract was thought to be normal and to stand in no relation to the arthritis. Also a few stools were examined from patients who had no joint trouble.

Methods are given below and a summary of results simply outlined at this point.

1. Patients with arthritis who respond to intestinal treatment exhibit luxuriant growths of intestinal bacteria both of the predominant type of *Bacillus coli communis* and also of spore-forming anaerobic bacteria.
2. No new specific pathogenic micro-organisms have been discovered.
3. The very large majority of spore-forming anaerobes correspond to *Bacillus aerogenes capsulatus*.
4. Wide variations exist in numbers of fecal bacteria found in different individuals, also in the same individual at different times; therefore numbers of bacteria present in any selected specimen of stool have slight significance unless excessively large. MacNeal[6] has exhaustively studied fecal bacteria of healthy men and confirms this observation of fluctuation in numbers of fecal micro-organisms.
5. Scanty numbers of fecal bacteria frequently are found in persons with arthritis who respond to intestinal treatment owing to the fact that cultures were taken at a time when fluctuations were at their lowest limit, due to purgation, diet and other treatment.
6. Patients with arthritis of other origins, also non-arthritic individuals, may exhibit all the peculiarities observed in those with arthritis of intestinal etiology, except that excessive numbers of bacteria are less persistently observed.

CONCLUSIONS

1. Patients with arthritis who respond to intestinal treatment habitually eat a little more than their digestive tract is able to properly care for, and intestinal putrefaction occurs with them in consequence very frequently and excessively, yet subject to usual fluctuations.
2. Excessive amounts of bacterial products, derived from activities of ordinary intestinal bacteria, find their way into the blood and produce arthritis in those persons who have susceptible joints, just as excessive amounts of uric acid derivatives in the blood produce joint changes in gouty individuals.
3. The exact identity of bacterial products that produce arthritis is unknown; nor is it understood whether they are derived from many species of bacteria or from some special organism, like spore-forming anaerobic bacteria. The presence of the latter in abundant numbers, and the fact that some of them are known to produce acute poisons, makes their rôle a suspicious one.

Baldwin[7] has studied the products of intestinal putrefaction as they appear in the urine of patients suffering with rheumatoid arthritis, and her observations are very interesting. All but two of the twenty-one cases examined showed either an excess of aromatic sulphates or else the presence of indican. Considerable variation was noted; in some instances indican was entirely absent, while other products of putrefaction, aromatic sulphates, were in excess of normal. In other instances one of the putrefactive products, indol, skatol or phenol, might be found in excess, while their total amount was not unusually great.

Comment should be made on the etiology of the cases which she examined as rheumatoid arthritis, with the assumption that they were all of the same origin. No data are given by her to show that several types were not included, some of them originating from intestinal toxemias, and others, in which the intestinal condition was secondary, to metabolic or neurotic disturbances, but which showed intestinal putrefactions from the inactive life and sluggish peristalsis that most arthritic patients complain of sooner or later. Her results are in accord with the fluctuating conditions known to exist in the intestine and serve to emphasize the probability that severe types of arthritis are made worse, and perhaps perpetuated after original causes have ceased to act, by intestinal putrefactions that have established themselves while the patients have been hopelessly crippled.

4. Clinical data not given in this article on account of their incomplete state suggest another type of arthritis originating in the intestinal tract independently of bacteria and due to defective digestion. Salient features of this type are its occurrence in old age, and the existence simply of chronic dyspepsia in characteristic cases. The type of joint changes in such patients is distinctly different from those typically associated with intestinal bacterial toxemias. In the former pronounced hyperthropic overgrowths of bone occur, while in intestinal toxemias of bacterial origin the damage is restricted mainly to soft tissues or very slight atrophy of bony trabeculæ. Defective metabolic processes going on in worn-out cells of the intestinal mucosa may conceivably lead to formation of unusual substances which act on joints, similarly as visible defects like cancer are associated with a toxemia from defective metabolic activities of cancer cells. It is admitted, however, that this origin of arthritis cannot at present be satisfactorily proved.

APPLICATION OF THE THEORETICAL CONCEPTION TO CONDITIONS EXISTING IN THE GASTRO-INTESTINAL TRACT

Some of the facts to be reconciled by these ideas may be illustrated by the following groups of cases: patients with fecal impactions who have severe arthritis; patients with fecal impactions who have no arthritis; patients with dilatation of stomach and enteroptosis with and without arthritis; patients with no severe intestinal symptoms, yet who have joint complications.

A starting point for explanation may be taken from conditions existing in the joints. Blood circulating through joints and containing irritating substances derived from the intestinal tract will or will not produce demonstrable lesions, according to the resistance of joint structures. In the majority of instances these are very resistant and withstand protracted, severe intestinal toxemias. The vital resistance of joint tissues also is constantly being exercised in other ways toward other bacterial toxins and metabolic substances of the blood, and in the large majority of all instances the joints are able to maintain their health in spite of adverse variable conditions.

---

[6] MacNeal, W. J., Latzer, L. L. and Kerr, J. E.: Fecal Bacteria of Healthy Men, Jour. Infect. Dis., April 1, 1909, vi, No. 2.

[7] Baldwin, Helen: Organic Acid in the Urine, Am. Jour. Med. Sc., 1904, new series, cxxviii, 1045.

It should be recalled that arthritis occurs as a complication of gonorrhea in only a very small percentage of cases, and is also associated with tuberculosis, pneumonia, scarlet fever, tonsillitis, typhoid fever, dysentery and other infections, always in very small percentage, too, of the total numbers of cases of these diseases.

When the severe toxemia of a pneumonia, scarlet fever, typhoid fever or dysentery subsides the arthritic symptoms subside also, if they have been present, as soon as the tissue cells are able to cope with and overcome the diminishing toxic influences of the blood. Likewise, when fecal impactions are removed and diminution in absorption of irritating substances from the intestine occurs, then there is also permanent subsidence of arthritic symptoms if they are present, because this extreme state is readily prevented again. Explanation of the observations enumerated, therefore, may be made as follows:

Patients with fecal impactions are absorbing large quantities of mild intestinal toxins that occasionally overcome fairly resistant joints, but in the majority of instances the tissues are able to resist even this excessive absorption.

Patients with dilatation of the stomach accompanied by putrefaction of gastric contents likewise are absorbing large quantities of putrefactive products, but joints are able to successfully resist in the majority of these instances, too. A few patients do succumb, however, and their arthritic condition may be helped by treatment of the stomach.

Patients with no severe intestinal disturbances must have particularly susceptible joint tissues in order to have arthritis as an accompaniment of such slight digestive defects, and very little can be accomplished for their cure.

DIAGNOSIS

Arthritis occurring with dysentery, typhoid fever or other acute conditions presents comparatively slight difficulties, but when caused by mild intestinal toxemias, histories related by patients suggest preliminary treatments, and diagnosis has to be made from the responses to these tests.

Obscurity of origin, therefore, is a prominent feature, and when no etiologic factors are discovered to account for the existing arthritis then daily irrigations of the colon with warm water are prescribed, together with some general tonic like elixir of iron, quinin, and strychnin phosphates, and after two or three weeks an idea may be obtained of the importance of the intestinal element. In favorable instances improvement takes place in the general condition of the patient, also in the skin and sclerotics of the eyes; the appetite is improved and joint pains begin to lessen. Further improvements as the result of more vigorous measures that will be described later make the diagnosis positive.

In some individuals, especially small, poorly developed women, the history of a slowly developing arthritis from no apparent cause, accompanied by a muddy, sallow complexion and lusterless eyes and loss of weight, permits a probable diagnosis immediately, but there are many other patients whose condition cannot be determined. Symptoms which are commonly associated with disorders of stomach and intestine frequently occur, but are too inconstant to have diagnostic value, the most striking peculiarities of this class being their insidiousness and absence of well-defined symptoms. The following list represents actual cases that have responded to intestinal treatment:

Case 1.—Appetite good; bowels moving regularly; slight pain at umbilicus at night; occasional periods of dizziness; no acute gastric or intestinal symptoms; fecal mass palpable in cecum.

Case 2.—Appetite good; bowels move two or three times daily; no gastric or intestinal symptoms; abdominal examination negative.

Case 3.—Poor digestion and continual craving for food; habitual constipation; no acute gastric or intestinal symptoms; abdominal examination negative.

Case 4.—Appetite moderate; bowels constipated; no gastric or intestinal symptoms; abdominal examination negative.

Case 5.—Appetite poor; bowels obstinately constipated; no gastric or abdominal symptoms; fecal masses palpable in colon.

Case 6.—Appetite moderate; bowels constipated; no gastric or abdominal symptoms; examination negative.

Case 7.—Capricious appetite, much fat pork eaten; bowels move once or twice daily; vomiting, severe abdominal pains, diarrhea; operation for gall-stones; complexion waxy, spleen enlarged; no fecal masses or abdominal tenderness.

Case 8.—Appetite moderate; bowels regular; no gastric or intestinal symptoms; abdominal examination negative.

Ether anesthesia conducted in the manner usually employed at surgical operations, but stopped as soon as muscular relaxation takes place, has different aftereffects on patients suffering with different types of arthritis.

For example, the patient with fecal impaction cited above experienced a short rise of temperature from normal to 102 F., also a brief attack of abdominal pain that required morphin, and slight increase in periarticular swellings following etherization for twenty minutes; while on the other hand, there may be very striking diminution of severe articular pains and surprising restoration of motion temporarily in affected joints after anesthesia.

These differences may possibly have diagnostic value in severe types associated with great pain and reflex muscle spasm. Moreover, etherization in such patients is often advisable, as Dr. T. S. P. Strangeways has pointed out, in order to differentiate between pure muscular spasm and adhesions of synovial membranes.

The effect of ether is evidently on articular sensory nerves and indicates differences of their irritability; consequently, it may perhaps also show pathologic conditions of unstable equilibrium in them by their unusual response, and suggests an important nervous element in underlying causes for such cases as respond to ether stimulation. Too few observations have yet been made to allow conclusions, and only the less frequent types in which articular pains and reflex muscle spasm are severe exhibit differences sufficiently well to be positively identified. Mention is made of this phenomenon, because there have been a few instances in which it has presented an additional clue of use in determining the nature of the arthritic processes.

PROGNOSIS AND TREATMENT OF ARTHRITIS ORIGINATING IN INTESTINAL TOXEMIAS, UNASSOCIATED WITH SPECIFIC PATHOGENIC ORGANISMS

Unusual intestinal conditions like fecal impactions that may be remedied, also many cases of intestinal disorders that have remained unrecognized and therefore neglected, offer favorable prognosis for the cure of associated arthritic disease. On the other hand, chronic intestinal troubles which have proven resistant to careful treatment and that are associated with very weak joints present an unfavorable outlook. Prediction whether a given case is curable or not often depends on the response to the first few weeks of preliminary treatment, and frequently cannot be told otherwise. Favorable prognosis always depends on the possibility of permanently diminishing the toxic substances in the blood. Attention, therefore, is directed logically toward diminishing the formation and absorption of toxic substances in the intestine and increasing the resistance of joints.

METHODS OF DIMINISHING THE FORMATION AND ABSORPTION OF INTESTINAL TOXINS

These include modifications in diet, introduction of antagonistic micro-organisms, intestinal antiseptics, stimulating drugs, stomach and colon lavage, abdominal supportive apparatus to correct visceral displacements and to overcome stasis of intestinal contents, surgical operations, colostomies, appendicostomies and operations on the stomach.

Diets are modified to lessen the quantity and nitrogen content of the food; buttermilk by means of its lactic acid organisms inhibits the growth of putrefactive anaerobes in the intestinal tract; various intestinal antiseptics may act in a somewhat similar manner. Medicinal tonics tone up digestive and absorptive functions and indirectly lessen putrefaction by minimizing the food available for putrefactive micro-organisms. Purgatives clear away accumulations of food that are fermenting and giving rise to toxic substances. Stomach or colon lavage also washes away decomposing food products and diminishes the formation of irritating bodies. Abdominal supports applied to individuals with very flabby, pendulous abdomens help to restore normal conditions and healthy action of stomach and intestine, and also minimize putrefactive changes; appendicostomies have been tried in severe cases of arthritis in order to secure more thorough irrigation of the colon and thus prevent absorption of intestinal toxins.

The aim of all treatments is removal of accumulations of food and putrefactive bacteria already lodged in the gastro-intestinal tract and prevention of reaccumulations, and simple measures which patients may continue to carry out themselves offer the most chances for cure.

In ordinary cases it is well to begin with purgation and colon irrigation until the intestine is thoroughly cleared, then to continue this treatment sufficiently energetically to maintain the advantage gained.

It is also well to put the patient to bed during the first week or so, while clearing the intestinal tract, and simultaneously to cut down the diet in order to lessen bacterial action to a minimum. A tonic may advantageously be given at the same time. In favorable instances, after two or three weeks, the joint pains begin to lessen, mobility increases and periarticular swellings disappear very slowly during the several months that follow.

In many cases improvement goes on for a time, then ceases, and symptoms may even recur. The probable explanation is that treatment has diminished absorption of toxic substances sufficiently to ameliorate symptoms partially, yet not enough to allow joint tissues to regain their normal function entirely. In these individuals operations which remove the absorptive function of the large intestine altogether, as colostomies, probably would be followed by complete subsidence of symptoms; but as recurrence seems likely to take place after colostomy openings have been closed, these operations should be seldom undertaken, because they are not permanent, and the discomfort attending them may be even worse than the condition which they are intended to relieve. They may be justifiable in rare instances, after all other methods have failed, with the hope of gaining temporary relief from the toxemia and allowing the tissues to recuperate sufficiently to resist new conditions in the future. Appendicostomies do not abolish the absorptive function of the colon as colostomies do, and consequently possess little advantage, if any, over purgation and intestinal lavage by rectum; moreover, they may be a considerable inconvenience.

Putrefactive changes taking place in the contents of the stomach, due to gastric dilatation, pyloric stenosis, congenital defects, or other pathologic states, require special treatment, differing according to the nature of the pathologic changes. The reader must be referred for special surgical and medical methods to text-books of surgery and medicine, because the subject is too comprehensive for this article.

The problem of avoiding reinfection of the digestive tract after clearing it of bacteria and decomposing foods has to be thought of, as bacteria constantly are being introduced through the mouth; therefore the sources for reinfection should be considered.

Bacteria get into the digestive tract continually with the food, and prevention of the spread of infectious diseases is a problem that public health authorities are dealing with. Milk and water supplies are subjected to rigid chemical and bacteriologic examinations in order to maintain a certain standard of purity and it is not inconceivable that such examinations may be further extended to include cold-storage products of various kinds in the future if it is proved that putrefactive anaerobic bacteria have sufficiently important pathogenic properties. It is well recognized by milk dealers that milk may spoil, although refrigerated, without becoming sour. These putrefactive changes of spoiling are due to growth of anaerobic bacteria that develop at low temperatures in which other micro-organisms cannot flourish. Eggs, also, that are kept in cold storage occasionally spoil from anaerobic bacteria and molds on the shells growing through the pores.

Cold-storage meats and fish seem open to the same dangers, although no definite statements can be made because investigation of bacterial changes of refrigerated meats have not been extensively undertaken; but it ~~seems~~ possible that the elaborate system of cold storage which has developed of late years may occasionally be responsible for intestinal putrefactions, and that nitrogenous storage products may sometimes contribute flourishing growths of spore-forming bacteria that have developed in the interval during which the products have been kept. This seems to apply especially to meats that have been removed, exposed for sale, and then again returned to cold storage, as bacteria may get well started in development when meats are exposed for sale in a warm atmosphere. These organisms are capable also of resisting unusual degrees of heat, and therefore may find their way into the alimentary tract as spores that are capable of further development. Certain cases of chronic arthritis may therefore rarely represent one of the special illustrations of this relationship between cold-storage methods and public health.

Bacteria, besides being taken with the food, also sometimes grow luxuriantly in the mouth cavity, and this fact must be given consideration when attempting to reduce intestinal putrefactions, and cases of pyorrhea alveolaris should receive treatment in order to diminish the numbers of anaerobic bacteria finding their way into the stomach.

METHODS OF IMPROVING THE DIGESTIVE FUNCTIONS OF THE GASTRO-INTESTINAL TRACT

These methods are well known to all physicians and are briefly outlined to show their application to special arthritic conditions discussed in this paper.

Normal secretory, absorptive and peristaltic functions of stomach and intestine may become deranged through accumulations of decomposing foods which exert a toxic influence; visceral saggings may sometimes result in harmful interference with blood-supply and nerve-supply of the organs; or dilatations may mechanically stretch and interfere with the function of the epithelial cells of the mucosa.

Digestive functions may be improved by treatment of each of these various pathologic states as they occur, but details of treatment for dilatations, muscular atonics, stenoses, adhesions, inflammations, displacements, ulcerations and malignant growths obviously cannot be given at length.

Mechanical stretchings and interference with blood-vessels and nerves due to relaxed abdominal walls should be treated with abdominal supports, as Goldthwait[8] recommends.

The behavior of epithelial cells of gastric and intestinal mucosa with regard to their secretory and absorptive functions depends largely on the chemical and nervous stimuli they receive, and maintenance of normal metabolic processes in them is of very great importance, as thereby bacterial decompositions are indirectly lessened and unusual substances due to defective metabolic processes are avoided. The lining epithelium is constantly being influenced through variable states of the blood, food, drugs and nervous impulses from the central nervous system; consequently foods and drugs, which may be changed at will, furnish an important means of regulating the health of these cells.

The most favorable conditions may be secured by the selection of a diet of suitable quality and quantity, low nitrogen content being one of the quality requisites; an amount that avoids accumulation of the unabsorbed excess indicating in a rough way the suitable quantity of food. Accumulations already present should be cleared away by means suggested previously. Dr. J. H. Kellogg has had success with many arthritic patients who exhibit intestinal toxemias by the use of a vegetarian diet of low nitrogen content. There seems to be no doubt as to the efficiency of this cure, but it is disagreeable for some persons and a limited mixed diet appears usually to be sufficient.

The effect of various drugs on digestion is too well known to require comment. The list includes preparations to increase secretion, lessen acidity, promote absorption, regulate evacuation, lessen movement, relax muscular spasm and inhibit bacterial action. Well-tried remedies like nux vomica, preparations of iron, sodium bicarbonate, pepsin, hydrochloric acid, calomel, saline cathartics and a few others fulfill most of the requirements.

The effect of mental depression from the gloomy outlook and chronicity of some cases has a very important influence on digestion of arthritic patients. This frequently is underestimated, but should be met with unusual optimism by the physician in order to overcome it. Maintenance of proper mental attitude of patients with chronic troubles is one of the most important and difficult problems of treatment. Patients who have responded partially to intestinal treatment and whose progress has become arrested should have occasional modifications made in their routine, as slight variations assist in maintaining greater activity of the intestinal mucosa and prevent a relapse into a chronic state again. By careful attention, and by means adapted to each individual, it seems possible to nurse the alimentary tract back to a normal state so that digestion by tissue cells is permanently improved and intestinal putrefaction permanently diminished, and the only essentials for treatment in most cases are a few simple remedies and sufficient consideration of each patient to accurately understand the existing state of affairs.

METHODS FOR RAISING RESISTANCE OF JOINT TISSUES

The only effective way known at present to increase joint resistance is to increase the individual's general health. Hygienic treatment advised for tuberculosis is especially well adapted to raise the resistance and increase the health of arthritic patients. There are local physical stimulants, as heat and cold, and electricity, that may be employed, but their administration frequently results in more harm than good from overstimulation of the tired-out tissues. The possibility of immunizing joints to bacterial and metabolic toxins has not yet been satisfactorily demonstrated.

Joints inflamed from intestinal irritants should be kept at rest during the active inflammatory period in plaster casts and afterward gently stimulated to increase the blood-supply locally after the intestinal tract has been cleared out and the patient's general condition has begun to improve. The blood may then be assumed to contain a diminished amount of toxin, and an increased supply of blood to the joints then becomes beneficial.

BACTERIOLOGIC METHODS

Results of examinations of stools must indicate conditions as they exist within the bowel, and not represent changes occurring subsequently; therefore the following precautions have been taken:

Stools were caught in sterilized tin cans and brought immediately to the laboratory, where they were kept at a low temperature and examined within a few hours.

For examination 0.5 gm. of fecal material was accurately weighed out, rubbed up in sterile normal salt solution, and a uniform suspension of precisely 50 c.c. obtained.

Plate cultures of litmus lactose agar, litmus lactose gelatin, and blood agar were inoculated with this 1/100 fecal suspension after thorough shaking and further dilution. The best plates were secured by 0.5 c.c. of 1 to 100,000 dilution and 1 c.c. of 1 to 1,000,000 dilution.

Spore-bearing anaerobic bacteria were determined by heating 10 c.c. of 1/100 fecal suspension in a capped tube in a water-bath for fifteen minutes at 80 C., after which 0.5 c.c. was plated with blood-agar, and 0.25 c.c. with plain agar, and 0.25 c.c. with a second blood-agar plate.

---

[8] Goldthwait, J. E., and Brown, Lloyd T.: The Cause of Gastroptosis and Enteroptosis, with Their Possible Importance as a Causative Factor in the Rheumatoid Diseases, Boston Med. and Surg. Jour., May 26, 1910.

Litmus lactose gelatin plates were kept three days at room temperature, then examined and counted. Litmus-lactose-agar plates were incubated at 37 C. for twenty-four hours before examination. Blood-agar plates were kept three days at 37 C. under anaerobic conditions, secured by passing hydrogen through Novy jars containing the plate cultures, then extracting the last traces of oxygen with pyrogallic acid and sodium hydrate.

Examinations at the end of three days were made and especial attention paid to hemolytic powers of the developing colonies. Oval colonies surrounded by distinct hemolytic zones developing from spores in blood-agar corresponded morphologically and culturally with *B. aerogenes capsulatus* or *B. perfringens*. Subcultures were made from typical colonies in each stool and further study of these confirmed the first impression that the large majority were *B. aerogenes capsulatus*.

Another paper, purely bacteriologic in nature, dealing with all the varieties of spore-forming anaerobic bacteria that have been found, may be published later, and for this reason only such points are mentioned in this article as bear on the clinical aspects of the relationship between joints and gastro-intestinal disorders.

It should be stated in summarizing that in a considerable proportion of intestinal cases improvement or cure may be effected; that the number is increasing as our knowledge of conditions and skill in applying simple remedies becomes extended, and that insistence should be made on early treatment before destructive changes have gone on that are beyond repair.

In conclusion I wish to acknowledge my indebtedness for clinical material to Drs. E. G. Brackett, Joel E. Goldthwait, Robert B. Osgood and Charles F. Painter, who have generously contributed private patients, and permitted the use of the orthopedic clinics of the Massachusetts General Hospital and Carney Hospital; also to Dr. Theobald Smith for valuable suggestions concerning bacteriologic methods.

8 Marlborough Street.

AN ACCURATE FORMULA FOR USE IN THE MODIFICATION OF COW'S MILK IN THE ARTIFICIAL FEEDING OF INFANTS

GEORGE REILY MOFFITT, M.D.
HARRISBURG, PA.

If the composition of milk from any source is definitely known, and known to be constant, a mathematically accurate formula may be devised by which artificial mixtures of any desired strength of fat, carbohydrates, and proteins may be compounded. The construction of such formulas is a somewhat long and tedious algebraic process, and when completed they are so complex that the compounding of milk mixtures by their use requires too much time and labor to be of service to the general practitioner.

With this fact in view, after having devised a formula based on 4 per cent. milk and 16 per cent. cream, I constructed a table of over 400 milk mixtures by ascertaining according to the formula, the amounts of milk, cream and milk-sugar required in compounding these mixtures, so that mixtures may be made up merely by reference to the table.

According to L. E. Holt[1] the composition of average herd milk is, fat 4 per cent., carbohydrates 4.50 per cent., proteins 3.50 per cent., etc., and the composition of what is known as 16 per cent. cream is, fat 16 per cent., carbohydrates 4.05 per cent., proteins 3.20 per cent., etc.

The formula based on milk and cream of this composition is calculated in the following manner:

Suppose a represent the per cent. of fat, b the per cent. of carbohydrates, and c the per cent. of proteins in any artificial mixture; that is, that which is commonly known as, for example, a 3-6-1 mixture (3 per cent. of fat, 6 per cent. of carbohydrates, and 1 per cent. of proteins) we term an a-b-c mixture. Now let x represent the per cent. of milk, y the per cent. of cream, and z the per cent. of milk-sugar necessary to compound such a mixture. The diluent will then be equal to $100-(x+y)$.

It is then obvious that

$$\frac{4x}{100}+\frac{16y}{100}=a \text{ or } x+4y=25a \tag{1}$$

$$\text{and}\ \frac{4.5x}{100}+\frac{4.05y}{100}+z=b \text{ or } 90x+81y+2{,}000z=2{,}000b \tag{2}$$

$$\text{also}\ \frac{3.5x}{100}+\frac{3.2y}{100}=c \text{ or } 35x+32y=1{,}000c \tag{3}$$

By subtracting Equation 1 multiplied by 8 $(8x+32y=200a)$ from Equation 3 we have

$$27x=1.000c-200a \text{ or } x=\frac{1{,}000c-200a}{27}$$

By subtracting Equation 3 from Equation 1, multiplied by 35 $(35x+140y=875a)$, we have

$$108y=875a-1{,}000c \text{ or } y=\frac{875a-1{,}000c}{108}$$

By substituting these values of x and y in Equation 2 we have

$$\frac{90\ (1{,}000c-200a)}{27}+\frac{81\ (875a-1{,}000c)}{108}+2{,}000z=2{,}000b$$

that is $40{,}000c-8{,}000a+7{,}875a-4{,}000c+24{,}000z=24{,}000b$

$$\text{or } z=\frac{a+192b-248c}{192}$$

We then have the values of x, y and z in terms of a, b and c; that is to say, we have the per cent. of milk, cream and milk-sugar necessary to make up an a-b-c mixture, and any values whatever (of fat, carbohydrate and protein percentages), such as 3, 6 and 1 may be substituted for a, b and c.

Our formula then is

$$\text{per cent. of milk}=\frac{1{,}000c-200a}{27} \tag{1}$$

$$\text{per cent. of cream}=\frac{875a-1{,}000c}{108} \tag{2}$$

$$\text{per cent. of milk-sugar}=\frac{a+192b-248c}{192} \tag{3}$$

To demonstrate the accuracy of the calculation in devising this formula, suppose we desire a 4-4.5-3.5 mixture, *i. e.*, a mixture containing 4 per cent. of fat, 4.5 per cent. of carbohydrates and 3.5 per cent. of proteins. It will be seen that this is cow's milk.

Substituting 3.5 for c and 4 for a in (1), we have

$$\frac{1{,}000\times3.5-200\times4}{27}=\frac{3{,}500.0-800}{27}=\frac{2.700}{27}=100$$

Substituting likewise in (2), we have

$$\frac{875\times4-1{,}000\times3.5}{108}=\frac{3.500-3{,}500.0}{108}=0$$

---

[1] The Diseases of Infancy and Childhood.

Substituting these values in (3), and also 4.5 for *b*, we have

$$\frac{4+192\times4.5-248\times3.5}{192}=\frac{4+864.0-868.0}{192}=0$$

showing that, in compounding a 4-4.5-3.5 mixture, we take 100 parts *milk*, no cream, no sugar and no diluent.

Now suppose we desire a 16-4.05-3.2 mixture (cream).

Substituting 3.2 for *c* and 16 for *a* in (1), we have

$$\frac{1{,}000\times3.2-200\times16}{27}=\frac{3{,}200.0-3{,}200}{27}=0$$

Substituting likewise in (2), we have

$$\frac{875\times16-1{,}000\times3.2}{108}=\frac{14{,}000-3{,}200.0}{108}=\frac{10{,}800}{108}=100$$

Substituting these values in (3), and also 4.05 for *b*, we have

$$\frac{16+192\times4.05-248\times3.2}{192}=\frac{16+777.60-793.6}{192}=0$$

showing that, in compounding a 16-4.05-3.2 mixture, we take 100 parts of cream, no milk, no sugar and no diluent.

In making a table of various mixtures from this formula, I have carried the calculations to a 0.1 per cent., *i. e.*, to three decimal places, which has shown results within 0.04 per cent. of perfect accuracy in all mixtures in which I have calculated the percentages of fat, carbohydrates and proteins from the amounts of milk, cream and sugar used in compounding such mixtures.

The following formula used in many hospitals, and I believe the most accurate one now in general use, is much less accurate than the preceding, especially in regard to the protein content:

$$C=\frac{Q\,(F-P)}{12}\qquad M=\frac{Q\times P}{4}-C$$

$$S=\frac{Q\,(CH-P)}{100}\qquad LW=\frac{Q}{10}$$

$$W=Q-(C+M+LW)$$

In this formula F represents the desired per cent. of fat, CH the desired per cent. of carbohydrates, P the desired per cent. of proteins, Q the quantity desired, C the amount of cream required, M milk required, LW lime water required and W water required.

Suppose we desire, say 24 ounces of a 3-6-1 mixture. By this formula we find that C = 4 ounces, M = 2 ounces and S = 1.2 ounces, i. e., the required amount of cream is 4 ounces, milk 2 ounces and milk-sugar 1.2 ounces. Now 4 ounces of cream contain 0.64 ounce of fat and 2 ounces of milk contain 0.08 ounce of fat, i. e., in a 24-ounce mixture by this formula there are 0.72 ounce of fat, exactly 3 per cent. (as desired) as seen by dividing 72 by 24.

Now 4 ounces of cream contain 0.162 ounce of carbohydrates and 2 ounces of milk contain 0.09 ounce of carbohydrates and we add 1.2 ounces of sugar, making in all 1.452 ounces of carbohydrates in the 24-ounce mixture or 6.05 per cent., as seen by dividing 145.2 by 24. Thus far the formula is quite accurate, the carbohydrates being inaccurate by only 0.05 of one per cent. But 4 ounces of cream contain 0.128 ounce of proteins, and 2 ounces of milk contain 0.07 ounce of proteins, i. e., 24 ounces contain 0.198 ounce of proteins or 0.825 per cent., as seen by dividing 19.8 by 24. Thus by this formula the proteins in this particular mixture are inaccurate by over 0.17 per cent.

By the table from the formula which I have described, 24 ounces of a 3-6-1 mixture require 3.5 ounces of milk, and 3.6 ounces of cream and 1.13 ounces of milk-sugar. Now 3.5 ounces of milk and 3.6 ounces of cream contain 0.716 ounce of fat, i. e., 2.98 per cent. of 24 ounces (inaccurate by but 0.02 per cent.) and 0.2377 ounce of proteins, i. e., 0.99+ per cent. of 24 ounces (within 0.01 per cent. of absolute accuracy), and these amounts of milk and cream plus the added sugar total in all 1.4333 ounces of carbohydrates in the 24 ounce mixture of 5.97+ per cent. (within 0.03 per cent.).

In calculating the amounts of the ingredients in 24 ounces of a 3.25-6-1.25 mixture by the old formula we arrive at an even more inaccurate result in regard to the proteins, for C = 4 ounces, M = 3.5 ounces and S = 1.14 ounces, and in 24 ounces, 4 ounces of cream and 3.5 ounces of milk give 3.25 per cent. fat (accurate) and 1.04 per cent. of proteins (0.21 per cent. out of the way), and these amounts of cream and milk with the added 1.14 ounces of milk-sugar give 6.08 per cent. of carbohydrates (0.08 per cent. off) practically a 3.25-6-1 mixture instead of a 3.25-6-1.25.

By our table 24 ounces of a 3.25-6-1.25 mixture require 5.328 ounces of milk, 3.528 ounces of cream and 1.056 ounces of milk-sugar, giving 3.24 per cent. of fat, 5.97 per cent. of carbohydrates and 1.24 per cent. of proteins.

The greatest inaccuracy encountered in the old formula, and in our table as well, is the last mixture in the table, viz., 5-7-3.50. By the old formula in a 24-ounce mixture we have 3 ounces of cream, 18 ounces of milk and 0.84 ounce of milk-sugar. These amounts in 24 ounces give 5 per cent. of fat (accurate), 7.38 per cent. of carbohydrates (0.38 per cent. off) and 3.02 per cent. of proteins (0.48 off), practically a 5-7-3 mixture instead of a 5-7-3.50 mixture as far as the proteins are concerned.

By our table we find in 24 ounces of a 5-7-3.50 mixture we require of milk 22.08 ounces, cream 1.92 ounces and milk-sugar 0.6 ounce. These amounts give of fat 4.96 per cent. (0.04 off), carbohydrates 6.96 per cent. (0.04 off) and proteins 3.47 per cent. (but 0.03 off).

Had the tables been carried out to one more decimal place all calculations would have been within 0.01 per cent. of absolute accuracy.

It will be seen, therefore, that the old formula is quite inaccurate in regard to the protein content which, having to do with the curd, should be the most accurate, especially when we are dealing with infants having digestive disturbances.

In speaking of proteins Holt[1] says:

> The modification of proteids is the most important change necessary in cow's milk, for it is the proteids which give most of the trouble to the infant's digestion. . . It is not enough to reduce the proteids to the average present in woman's milk, *i. e.*, 1.5 per cent. During the early months the percentage should be less than this. . . I believe the secret of success in feeding cow's milk is to begin with the proteids so low as not to disturb the infant's digestion, and then slowly, but steadily, raise the quantity. . . Except to start with too high proteids, no more common mistake is made than to continue long with too low proteids. Anemia, malnutrition, and, I believe, not infrequently scurvy, are seen as a consequence of this practice. The gradual increase is therefore just as important as the low beginning.

In the table I have not considered diluents, for it is evident that after ascertaining the amounts of milk, cream and milk-sugar necessary for a certain amount of a given mixture, a sufficient quantity of water or other diluent is added to the milk, cream and sugar to make the required amount. If lime-water is to be used, 5 or 10 per cent., as desired, is added before adding the diluent.

If barley water or other cereal water is used, as recommended by many to assist in breaking up the curd, it, too, may be added in the quantity desired before adding the water. Since barley water contains of fat 0.05 per cent., carbohydrates 1.63 per cent. and proteins 0.09 per cent., (Holt), when it alone is used as the diluent, a reduction should be made in the carbohydrate per cent. of the formula; e. g., if a 3-6-1 mixture is desired the ingredients of a 3-5-1 mixture should be used, the percentage of the carbohydrates being subsequently raised by the addition of the barley water. The same point must be observed when adding the various dextrinizing powders to the milk mixtures. The dextrinizing process raises the sugar content about 2 per cent., so if a 3-6-1 mixture were desired, the ingredients of a 3-4-1 mixture are dextrinized.

SCHEDULE FOR AN AVERAGE HEALTHY INFANT, SHOWING PERCENTAGES OF FAT, SUGAR AND PROTEIDS, AND THE QUANTITIES

Age.	Percentages of— Fat.	Sugar.	Proteids.	Quantity for one feeding. Ounces.	Grams.	No. feedings in 24 hours.	Interval by day.
Premature infants	1.00	4.00	0.25	¼ - ¾	7-22	12-18	1-1½ hours
First to fourth day	1.00	5.00	0.30	1 - 1½	30-45	6-10	2-4 "
Fifth to seventh day	1.50	5.00	0.50	1 - 2	30-60	10	2 "
Second week	2.00	6.00	0.60	2 - 2½	60-75	10	2 "
Third week	2.50	6.00	0.80	2 - 3½	60-110	10	2 "
Fourth to eighth week	3.00	6.00	1.00	2½ - 4	75-125	9	2½ "
Third month	3.00	6.00	1.25	3 - 5	90-155	8	2½ "
Fourth month	3.50	7.00	1.50	3½ - 5½	110-170	7	3 "
Fifth month	3.50	7.00	1.75	4 - 6	125-185	7	3 "
Sixth to tenth month	4.00	7.00	2.00	5 - 8	155-250	6	3 "
Eleventh month	4.00	5.00	2.50	6 - 9	185-280	5	4 "
Twelfth month	4.00	5.00	3.00	7 - 9	220-280	5	4 "
Thirteenth month	4.00	4.50	3.50	7 -10	220-310	5	4 "

In the modification of cow's milk by any formula it is essential to know the composition of the milk and cream used and while it is true that average herd milk is usually 4 per cent. and gravity cream is usually 16 per cent. it is advisable to make the simple fat estimations with the Babcock centrifuge from time to time, for if the fat percentage is correct, the amounts of the other ingredients will also be correct.

Holt[1] recommends the accompanying schedule for an average healthy infant, showing percentages of fat, sugar, and proteins, and the quantities.

It will be seen by this schedule how important it is to have great accuracy in respect to the proteins.

A few of the mixtures from the table calculated by the formula which I have described appear below.[2] If the per cent. or parts per hundred of milk, cream and milk sugar necessary to make up the mixtures were actually given in the table, the decimal point would be two spaces to the right of what it now is.

As the table is, the amounts of milk, cream and milk sugar in a certain amount of any mixture are found by multiplying that amount by the figures opposite the mixture in the table, for example, suppose we desire 36 ounces of a 3-6-1 mixture. We find that the three numbers in the table opposite 3.00-6.00-1.00 are 0.148, 0.150 and 0.047. By multiplying 36 by 0.148 we have the amount of milk, multiplying by 0.15 we have the amount of cream and by 0.047 the amount of milk sugar in ounces. Or suppose we desire 850 gm. of a 3-6-1 mixture. By multiplying 850 by 0.148 we have the amount of milk, by 0.15 the amount of cream and by 0.047 the amount of milk-sugar in grams.

One-half the quantity of cane-sugar may, of course, be used in the place of milk-sugar.

1705 North Front Street.

---

[2] The following list of mixtures has been selected from a very elaborate table including over 400 mixtures, which I have calculated by the formula described above, and is given here to convey some idea of the character of the complete table which will be published with the reprint of this article:

Mixture.— Fat.	Carbohydrate.	Protein.	Milk.	Cream.	Sugar.
0.50	4.00	0.25	.055	.017	.036
0.75	4.00	0.25	.037	.037	.036
1.00	4.00	0.25	.018	.057	.036

THE RADICAL CURE OF MALARIA; ITS IMPORTANCE AND HOW IT IS ATTAINED *

SEALE HARRIS, M.D.
Professor of Practice of Medicine and Clinical Medicine, University of Alabama; Visiting Physician, City Hospital
MOBILE, ALA.

Science has almost solved the problem of malaria in all its phases; but, despite our almost complete knowledge of the life-history of the malarial parasite both in man and in the mosquito, despite our familiarity with all the manifestations of the disease, and despite the fact that every physician knows that it is easily prevented and ordinarily yields to treatment, malaria, though decreasing in severity and frequency, continues as one of the most prevalent diseases in many localities of the United States, in some places its mortality rate amounting to 25 per cent. of the total number of deaths.[1]

According to the statistics obtained from the last census, the number of deaths from malaria in the United States in the year 1900 was 14,909. The following states showed the greatest mortality: Arkansas leading with 1,730; then Texas, with 1,331; Alabama, 1,055; Louisiana, 1,030; Georgia, 1,011; Tennessee, 987; Missouri, 965; Mississippi, 938; South Carolina, 749; North Carolina, 527; Illinois, 497; Virginia, 409; Indiana, 340; and New York, 308.[2] These statistics are of question-

able value, since they are largely derived from information obtained by the census enumerators in the rural districts, and no doubt many deaths reported from malaria were due to typhoid fever and other diseases. It should be remembered, however, that malaria as a complication of pregnancy and of a number of diseases, and as a cause of arteriosclerosis and nephritis, is responsible for many deaths which are ascribed to other causes. It would therefore seem that these statistics do not overestimate the number of lives sacrificed to this easily preventable and curable disease.

The simple statement of the number of deaths from malaria does not half tell the story of its ravages. Its expense to the people of the United States is appalling. It is estimated that malaria costs our nation from $50,000,000 to $100,000,000 annually.[3] Dr. Albert Woldert, of Tyler, Texas, after a careful study of the mortality and morbidity rates of Texas, estimates that malaria costs that state more than $5,000,000 per year.[4] Assuming that the United States census mortality rates are as correct for Missouri as for Texas, and that the morbidity rates are in the same ratio, malaria taxes the state of Missouri more than $3,000,000 annually.

MALARIA UNNECESSARY

The unnecessary burden of malaria can be relieved simply by radically curing those suffering from the disease, but, strange to relate, this most important point has been most neglected. Malaria can be entirely eradicated, in one year, in any community, without regard to the number of anophelines present, if every person having the disease will take quinin long enough to be completely cured.[5] It is man, and not the mosquito, that carries malaria through the winter, thus perpetuating the disease. Therefore, the most important measure in the crusade against malaria is its radical cure, and it is this phase of the subject that I shall discuss.

The average physician does not regard malaria as a serious disease. He relieves the acute symptoms in a few days and when a patient dies of malaria he feels that the patient has neglected himself. It is in the most malarial regions that the disease is most lightly regarded. We should emphasize the seriousness of the disease and the importance of its radical cure.

The complications of malaria which result from our failure to cure our patients are responsible for more deaths than the acute and pernicious forms. The manifestations of malaria, like those of syphilis, are protean, and no organ in the body is exempt from its ravages. Its most marked effect is seen on the renal organs[6] and the vascular system.[7] As a consequence, in malarial regions, the general death-rate is high and the mortality from nephritis and the various forms of paralysis is inordinately increased.

While there is certainly no relationship between malaria and syphilis, and the etiology, histology and pathology of the two diseases are widely and essentially different, yet many of the clinical manifestations are analogous. I realize that it is an "odious comparison," but it is made to emphasize the importance of the prolonged treatment of malaria.

Malaria and syphilis are general or systemic diseases, the organisms and their toxins circulating in the blood; both are inoculable; they have a definite period of incubation; in the secondary stage of syphilis there may be a fever of a remittent type (I saw a case of syphilis in the secondary stage, with daily rise of fever to 103 to 105 F., in which a clinical diagnosis of typhoid or malaria was made, but the laboratory proved it to be syphilis); there may be *skin manifestations in malaria*;[8] the tendency to chronicity is marked in both, as well as the proneness to involvement of many different organs; there may be prolonged periods of latency in malaria as in syphilis; no two diseases produce more nearly similar or more serious effects on the vascular system and renal organs; malaria is sometimes a cause of ulcerative keratitis,[9] optic neuritis, the acute psychoses,[10] sclerosis of the cord,[11] and even progressive paralysis;[12] in both diseases we have drugs which are almost specific in their action, but in order to get the best results treatment in both diseases must be begun early and continued for a long period.

Relapses, which result directly from our failure to cure our patients, may occur as recrudescences of the fever soon after acute symptoms, as exacerbations during the chronic course of the disease, or as distinct attacks during latency. Reinfections are usually relapses or recurrences.

Celli[13] regards a relapse in malaria as the recurrence of symptoms at any time within one year from July 1. Reinfections occur after one year. Undoubtedly relapses have been observed several years after infection, and reinfections may occur in less than a year, but Celli's rule is a safe one to follow. If we adopt this rule and keep records of our cases we shall find how few of our malarial patients we radically cure.

The world owes a debt of gratitude to Manson for his self-sacrificing work in studying malaria, and he is rightly regarded as one of our greatest authorities on the disease; yet even he did not cure the disease in himself when first infected. He allowed himself to be inoculated by infected anophelines on Sept. 10, 1900, and had a relapse on May 30, 1901.[14] Authentic cases of relapse after three years of latency have been reported.[15]

There would be but little chronic malaria if the acute cases were cured, but there are to-day probably two or three million persons in the United States who are harboring malarial parasites. Headaches, neuralgias, neuritis,[10] gastric disturbances and acute diarrhea are among the most frequent symptoms of the chronic or "masked" forms. Indeed, malaria may simulate almost any disease. Craig[16] reported fourteen cases of malaria which had been diagnosed as pulmonary tuberculosis.

TREATMENT

All authorities agree that quinin is almost a specific in malaria, when treatment is begun early and continued long enough to eradicate the parasite from the system completely, though there are differences of opinion as to the time of administration, the dosage, and duration of treatment.

Given a patient in a hospital where his symptoms can be watched, and with competent microscopists who can make repeated daily examinations of the blood, the rule "no parasites, no quinin" is best; but, practically speaking, nine-tenths of the physicians, in the rural districts where malaria abounds, have not microscopes, or the time to make blood examinations; therefore the diagnosis must be made from the symptoms and quinin administered at once. In malarial districts it is a good rule, when in doubt, to give quinin and watch for symptoms of other diseases. Quinin does but little harm in any disease, and it may do a great deal of good in eliminating malaria, which may complicate and make more serious any other disease.

The microscope is not always a criterion as to chronic malaria, because undoubtedly the disease does exist without the presence of parasites in the peripheral circulation. Now, however, that we have, in most states, laboratories connected with our state boards of health, where examination of blood is made free, and many private laboratories, where specimens may be examined for a small fee, the physician who is not equipped with a microscope should carry a few slides at all times and get a specimen of blood from cases of suspected malaria immediately before beginning the administration of quinin. He can get a report in two or three days, by telegram in twenty-four hours, if the symptoms are urgent. The few doses of quinin given before the report is received cannot injure the patient, and if the parasites are present the drug should be continued until a cure is effected.

There are differences of opinion as to the most favorable time of the day to administer the quinin. Torti's, also called the Roman, method of giving one large dose, 15 or 20 grains, several hours before the expected paroxysm, based on the theory that the best effect of the quinin is obtained during sporulation, when the youngest forms are free in the blood-stream, has many followers in the South. Some of the older physicians still follow Sydenham's method of giving one or more large doses during the remission or intermission of the fever, when the drug is less apt to produce nausea or other discomfort. In my opinion the best method, that employed by Gorgas, Deaderick,[17] Craig,[18] Rogers[19] and other authorities, and the method which I have employed for fifteen years, is to keep the patient continuously under the influence of quinin, by giving him small doses every four hours, both day and night, with perhaps an extra dose about four hours before the expected paroxysm.

In the tertian and quartan forms 3 or 4 grains every four hours is sufficient, but in the more resistant estivo-autumnal variety 5 grains every four hours will be required. This dosage should be kept up for three or four days after the fever has subsided; then half the quantity should be given for two weeks. I do not believe that there is ever any occasion for giving more than 30 grains of quinin a day, and the very large doses are regarded by some authorities as positively dangerous.

In the acute and severe estivo-autumnal fevers the quinin may have to be kept up in maximum doses (30 grains daily) for several weeks, because the crescents, or gametes, are very resistant to quinin. In 1904 I reported a case of a negro girl, aged 14, who had crescents in her blood after the administration of 4 grains of quinin, in solution, every four hours for twelve days.[20] Darling, of the Canal Zone, in the Section on Practice of Medicine last year reported a number of cases in which gametes remained in the blood from two weeks to twenty-five days in spite of the daily administration of 30 grains of quinin.[21] Craig has also made extensive studies of the gametes in the peripheral circulation for varying periods of time after the use of quinin.[22]

In the acute cases of all types of malaria it is important for the patient to remain in bed for several days, because undoubtedly the best effect is obtained from quinin while the patient is at rest.

How long should the quinin be continued to attain a radical cure? Deaderick[17] says: "A few days' treatment with quinin no more cures malaria than does a few weeks' rubbing with mercury cure syphilis." He continues the quinin in 15-grain doses on two successive days of each week for two or three months. Craig, Rogers and other well-known authors also advise a modification of Koch's method.

In Italy small daily doses (6 grains) are given for three months after the acute symptoms have subsided, just as it is given to entire communities for the prophylaxis of the disease.[23] No doubt the prophylactic doses effect cures in many chronic cases, since in some localities the disease has been almost entirely eradicated and in five years the Italian death-rate from malaria has been reduced three-fifths (Thayer).

Ross[24] says: "To extirpate the parasite in a patient demands four months' assiduous cinchonization," and I believe that this is the safest rule to follow.

Thayer advises the small daily dose (6 grains) rather than the large intermittent doses. My experience has been that the small daily doses (3 grains night and morning) are efficient and are better borne than the large doses repeated at intervals of several days. I have also found that the memory test of giving quinin on certain days of the week or month is too severe for malarial patients, and they frequently give it up in disgust, while by taking it two or three times a day they form the quinin habit and will keep up the drug for even longer periods than is desired.

PROPHYLAXIS

It is not my intention to suggest any less vigilance in destroying anopheles mosquitoes and their breeding-places, and I would urge that those measures be employed to the fullest extent possible. I do maintain, however, that the most important and the most practical measure, at this time, in the crusade against malaria, is the radical cure of those harboring the parasites, because every patient cured means one less focus of infection. We should remember that there are malaria carriers as well as typhoid carriers, and that one is as dangerous to the community as the other. We should not forget that the patient with the parasites of malaria in his blood may infect mosquitoes and transmit the disease to others, just as in yellow fever, and that malaria may be as serious a disease as yellow fever.

I believe that we should at once institute a campaign against malaria. It offers the most brilliant results of any of the public health problems now confronting us.[25] A campaign of education should be begun with the medical profession, because physicians as a class, and particularly those residing in malarial regions, do not appreciate the seriousness of malaria, or the ease with which it may be eradicated. The public should be educated by means of popular addresses and literature on the subject should be placed in the hands of every one residing in malarial districts. Malaria, being both infectious and contagious, should be classed as among the reportable diseases, and the state and county boards of health should lead in the fight. Municipalities, counties and states should be called on to furnish money to purchase quinin to cure the indigent sufferers from malaria and to destroy the anophelines and their breeding-places. Philanthropists should be urged to aid in this fight against one of the greatest enemies to mankind. Money spent in eradicating malaria will yield greater returns than any other philanthropy.

It is no idle dream to hope that the blot of malaria may be erased from the fair name of our Southland and from the Mississippi and Missouri valleys, where the disease is most prevalent. Our government has given us an example of what may be accomplished even in the tropics. Gorgas,[26] with the resources of our great country to aid him, when he applied the knowledge of the mosquito transmission of disease and eradicated yellow fever and malaria from Havana and the Canal Zone, made conquests which should be regarded as among the greatest in the history of the world, victories that mean more for the welfare of nations than have ever been achieved in war.

ABSTRACT OF DISCUSSION

Dr. Charles MacLellan, Chicago: In my opinion the theory of the anopheles being the only carrier of malaria is wrong; malaria is sometimes found in northern latitudes where there are no anopheles. I remember, while in the Orkney Islands, being called to see a sick man, suffering from a severe attack of malaria, and in that region mosquitoes are unknown. Of course the gnat, of the same genus, exists in the British Isles. A second case in a man who had never been off the island came to my knowledge. Of course, we know that the anopheles is the great carrier of malaria, but there must be a first cause in the mosquito region.

With regard to the method of treatment, the administration of quinin in capsule or powder, is not an efficient manner of getting at the disease for its eradication. I believe the best method of administering this agent is in a solution of sulphuric acid. I have in mind one patient who gave a history of malaria, having been ill over a week and who had taken from 6 to 10 grains of quinin in capsule 3 times a day, without result; on giving him 2 grains of quinin 3 times a day, of the solution just mentioned, he escaped the chill on the second day and it did not return.

Dr. Arnold Traubitz, Neelysville, Mo.: I live in a district where every patient who goes to a physician's office is supposed to have malaria, and, having treated many of them with success, I cannot agree entirely with the method of treatment just outlined. Giving quinin 3 times a day for 3, 4 or 5 months is wrong; the patients cannot stand this treatment because of the resulting gastric disturbances. My method of treatment of the malaria that shows itself every other day, or every third day, consists in giving 4 or 5 hours before the expected attack, in one dose, from 25 to 30 grains of quinin; I give this about 4 or 5 hours before the chill is expected. Even with such a dosage, often I do not get the results I expected. I have given as much as 60 grains at one time. I find then that the patient always misses the next chill. It should be remembered, however, that the chill cannot be broken on the same day that the quinin is administered. Some patients cannot stand quinin every 4 hours. The main thing in the treatment of this disease is elimination; the stomach must be in proper condition to eliminate and cause a proper action of the gall-bladder; otherwise patients must be kept on quinin indefinitely, a procedure which they cannot stand. The long-continued use of quinin is unnecessary. In treating malaria, the digestive system should at first be placed in a receptive condition for the specific; after the administration of the quinin the annihilated bacteria should be excreted from the system.

Dr. W. E. Chapman, Sheboygan, Mich.: In 1902, I served as contract surgeon in the Philippines, and was called to treat many cases of malaria. In one very stubborn case, running over a period of several weeks, I kept increasing the dose in capsules until 70 grains were taken daily, vacillating in my diagnosis between malaria and typhoid fever, as the quinin did not influence the fever, and at last being assured of my diagnosis, I dissolved 150 grains of sulphate of quinin in a weak solution of hydrochloric acid, and gave it to the patient in 4½ hours. The next morning the man was free from fever; he had a beautiful eruption and was very deaf, but for the following 3 months, while he was under my care, he had no more chills or fever.

Dr. I. J. Wolf, Kansas City, Mo.: One thing to remember, and one that Dr. Harris laid stress on, was that malaria may assume the picture of almost any organic disease we know or can name. I remember one case of intermittent pneumonia which was due to the malarial parasite. I have in mind also another case in which the malarial parasite was responsible for an acute attack of enterocolitis in a baby during the summer months. The question at first arose: Was the trouble due to a faulty diet? I had just read an article on malaria in children and I suspected that something of this nature was the trouble. An examination of the blood showed that it was swarming with malarial parasites. The proper administration of quinin brought an end to this attack of enterocolitis. I do not believe that the treatment of malaria differs in any way from the treatment of any other disease. One should never have a stereotyped method of treatment of this, or any other, disease. One physician spoke of giving enormous doses of quinin, while another referred to the giving of small doses. Whether the dose of quinin should be large or small depends on the patient who is to receive the remedy. It is very important that the question of the total eradication of the disease should be borne in mind, as well as the immediate cure. One should not be satisfied with the production of the latent stage—but should be satisfied only with cure. Thousands of dollars have been spent on the eradication of the mosquito; if a fractional part of this money had been spent on the cure of the patient much good could have been attained. Without a malarial patient, the mosquito could not be a conveyer of this disease.

Dr. Vernon Blythe, Paducah, Ky.: One thing that has not been sufficiently discussed is the difficulty of diagnosis of malaria from certain other fevers, especially typhoid. I am of the opinion that the giving of quinin in typhoid, which is done so much, does harm. I think that when a definite quantity of quinin has been given to a patient suspected of having malaria, and in those cases in which there is a question in diagnosis between malaria and typhoid, and when the quinin has had little if any effect on the temperature, the amount should be cut down to the minimum. The use of quinin in typhoid I believe to be distinctly harmful, especially to the circulatory and nervous systems. This drug has little effect on the temperature of typhoid, and I wish to enter a protest against its use in treatment of this disease.

Dr. S. P. Child, Kansas City: As Dr. Harris has stated, there is great confusion at times and great difficulty in making a positive diagnosis between malaria and typhoid because of the absence of findings in the peripheral circulation. Physicians in Kansas City get many cases of malaria from Missouri towns and elsewhere; these places have many mosquitoes; a large number of cases appear in children and these have proved to be mainly of the estivo-autumnal type. Some cases, in which the frequent examination of the blood has shown the malarial parasites, have previously been diagnosed as pernicious anemia. In a period of six months at the Mercy Hospital in Kansas City, a hospital for children, we have had 7 cases of malaria, diagnosed by the blood findings, with one death. There was one case of typhoid fever during this period. Among these 7 cases there were 3 of the estivo-autumnal type, and the blood findings were suggestive of pernicious anemia. It was found that small and repeated doses of quinin by mouth would not cause a destruction of the organisms; therefore, we resorted to hypodermic medication of a combination of urea and quinin hydrochlorate; in every instance, as was shown by the result, we were justified in resorting to regular and systematic hypodermic medication. Only in 2 instances were large doses required and then we gave up to 12 grains every 2 hours hypodermically, in the gluteal muscles. In no case did we produce true cinchonism. These patients should be watched for several months before it is announced that a positive cure has been obtained.

[25] Harris, Seale: Some Problems in Medicine which Affect the Prosperity of the South, Jour. Southern Med. Assn., April, 1909.

[26] Gorgas, W. C.: Malaria in the Tropics, The Journal A. M. A., May 12, 1906, p. 1416; Ann. Rep. Dept. of Sanitation, Isthmian Canal Commission, 1908, Government Printing Office, Washington.

DR. C. C. BASS, New Orleans: In my section of the country we see malaria every month and every year; the disease there appears in two varieties. I believe that there is an impression among almost all the physicians practicing in that section of the country, that of all the specifics in medicine, one that is as nearly a specific as any is quinin in treatment of malaria. A second impression that prevails is that in every patient who has malaria to such an extent as to give symptoms the plasmodium can be demonstrated in the blood by the use of the microscope.

DR. JOSEPH H. PRATT, Boston: Many of the conditions accompanying malarial infection should not be confused with the infection itself. Various diseases of the nervous system are frequently attributed to malaria on insufficient evidence. I recently saw a typical case of migraine in a patient from Illinois who had been treated for years for chronic malaria. A physician whom she consulted in Boston concurred in the diagnosis and on examination of her blood reported that it was "swarming with parasites." This patient, now 30 years of age, has not had chills or fever since childhood. When I examined her she was not anemic and the spleen could not be felt. There were no malarial parasites in the blood. Certainly a medical man must be thoroughly imbued with the false idea that all sorts of nervous disturbances may be the manifestations of malarial infection to regard for a period of ten years a case of migraine as one of malaria in a patient who did not present a single symptom that was characteristic of the latter disease. It is a common error for the inexperienced man to mistake malarial parasites for blood platelets in stained specimens. There is no doubt, that even at present, many physicians in all parts of the country mistake typhoid, tuberculosis, and septic conditions for malaria. Many base their diagnosis of malaria solely on the presence of chills and fever. I remember a striking case in which the error was not discovered until revealed by autopsy. The chart was typical of malarial fever. The paroxysms, consisting of chills, fever, and sweating recurred regularly. Large doses of quinin had been given and although the fever did not yield, the physician in charge held to his diagnosis of malaria. Autopsy showed a purulent thrombus which filled the portal vein. Such experiences as these teach two lessons. 1. We should awake to the truth, so clearly stated by Osler, Craig and others, that a fever which does not yield to small, repeated doses of quinin properly administered with the patient confined to his bed, is not malaria. 2. Blood examinations are of no value unless made by a competent person.

DR. G. C. SMITH, Boston: The idea of a man from Boston speaking on the subject of malaria seems strange, especially as there is so little of the disease in Massachusetts. I know how prevalent the disease is in the middle west and south, but we in the New England states do encounter an occasional case We have some cases imported from the west and south, and some patients have appeared here who reported that they were cured of malaria. It has been my fortune to see many such cases in consultation. I can corroborate the remarks of Dr. Pratt. During the past year I distinctly remember 3 cases of pyelitis of chronic form which had been diagnosed as malaria, and 2 patients with suppurative disease of the gall-bladder which had been treated with quinin, under which the chills and fever had subsided. The patients were supposed to be cured of the malaria. The attacks came and went. There was a repetition of the administration of quinin and always with the same results—temporary disappearance of the chills and fever. Of course the patients did not improve because of the quinin they took. I believe that there are so many suppurative affections which are liable to be misinterpreted as malaria, that this point should be emphasized.

DR. J. A. WITHERSPOON, Nashville, Tenn.: I rise to insist on a never-ceasing effort on the part of the physician to teach people how to rid themselves of this fell destroyer. Notwithstanding the fact that our brothers in Boston may find cases in which errors in diagnosis have been made, such as pyelitis and infected gall-bladders, if they would only visit the delta of the Mississippi River they would have more respect for the old-fashioned malaria of which Dr. Harris has spoken. I will even go farther and say that we realize the mistakes that are made, and that blood counts are necessary, but from my own personal observation I believe that there is no better class of men who can handle malaria in general than those men who practice medicine in the south where this disease is so prevalent. It is a mistake to say that down there the diagnosis is made largely on hearsay and without proper examination. There was a time when, all over the country, the physician looked at the patient's' tongue and felt of the pulse and made a diagnosis; that is not true today in my section of the country. In spite of the statements made by Osler, Pratt and others that if a fever does not yield after administration of a few doses of quinin it is not malarial, I wish to state that no more false statement was ever made in the Mississippi Valley than that; it certainly is not true. I agree with Dr. Harris that the early disappearance of the malarial plasmodium from the peripheral circulation in the latent cases of the disease does not mean that they are gone entirely from the circulation; one may repeatedly examine the blood and not find them; but they are still to be found in the deep-seated organs, lying there dormant, especially in the spleen and other organs. It requires several months of continuous treatment to eradicate the disease in such cases. It seems to be almost impossible to eradicate malaria of latent form if such patients are allowed to be up and around. We are up against a problem that costs not millions of dollars only, but hundreds of lives throughout the country because the disease is not properly treated in the latent stages.

DR. C. SHATTINGER, St. Louis: The question in mistaken diagnosis from Boston is interesting, but I should like to bring up a reverse condition, and relate a case which occurred in Kentucky where malaria is so prevalent, and where physicians might be supposed to be familiar with the disease. This patient, a woman, suffered for a long period of time and it was believed that she had some ovarian or uterine disease, and hysterectomy was decided on. By accident she happened to fall into my hands. Examination of the blood revealed swarms of the plasmodia. In this case 35 grains of quinin were given every 24 hours and it was necessary to keep this up for a period of 10 days before the paroxysms ceased. This corroborates Dr. Witherspoon's announcement that we cannot control the disease always by the administration of 1, 2 or 3 large doses of quinin.

DR. R. ALEXANDER BATE, Louisville, Ky.: A point brought out by Dr. Harris that impressed me very much was the quiescence of malaria for a period of 3 years. I do not wish to question this statement, but I wish that Dr. Harris would tell us why such a statement should be sustained. It is believed that the malarial protozoon segments in the light; therefore, this accounts for the immunity sustained by some of the negro race. I can readily understand why the protozoa might remain in a quiescent state for a reasonable period of time. But how can Dr. Harris explain that reinfection did not take place and that there was not a relapse? How can he explain or exclude the possibility of reinfection? It was suggested by one speaker that the malarial protozoa are in the deeper structures, not so much in the peripheral circulation, and away from the light; but how can this be demonstrated?

It is of course beyond question that the mosquito is the active agent in the cause of malaria; but I think, with certain Italian observers, that the mosquito is not the only source of infection. In recent papers the statement has been made that we must eradicate the swamps before malaria can be eliminated from a district infected with this disease.

With regard to the periodicity of malaria, it should be remembered that there are many diseases of metabolism which show periodicity. Certain materials accumulate in the system unutil a period of toxicity is reached.

Dr. Arthur G. Bell, Dallas, Texas: A case in a blacksmith, weighing 250 pounds, in my district was diagnosed as hip-joint disease. He had been a confirmed invalid for several years, and simply directed the work at his shop. He told me that some physicians had diagnosed his case as rheumatism and that others had pronounced it hip-joint disease. One surgeon stated that the Y-ligament had been bound down by adhesions, and that nothing would give relief except an operation. I examined the man carefully. I decided that his facial expression indicated chronic malarial cachexia. He ridiculed the idea, giving no history of malarial complications. Nevertheless, I directed him to take 4 grains of quinin, 3 times daily, till an ounce had been taken. After this simple treatment had been continued for some time the trouble disappeared like magic. The ligaments soon assumed their normal actions. Frequently I have seen physicians who lived in the same state or county disputing vehemently whether it was right to give quinin in malarial hematuria or not. One says that if you give quinin in malarial hematuria the patient will die. The other says that if you don't give quinin the patient will die. Some communities would not tolerate a doctor if he gave quinin in such cases, and others would discredit a physician if he did not. The text-books agree no better than the practitioners. One says quinin. The other says no quinin. It is said, however, that in cases of malarial hematuria, in which there are red corpuscles in the urine, quinin is indicated whereas when there is hematin, or hemoglobin in the urine no quinin is safe. When I formerly took steps to stop the hemorrhage from the kidneys I usually signed an extra death certificate. I have not attempted to stop the hemorrhage from the kidneys in my late cases. I wish to call attention to the fact that in the disease called malarial hematuria there seem to lurk two distinct diseases—one demanding quinin and the other no quinin. Will some one make the differentiation?

Dr. Isaac Ivan Lemann, New Orleans: One cannot be sure of one's diagnosis of malaria without an examination of the blood for the plasmodium. This is a point that cannot be put too strongly. Dr. Harris is probably correct in looking on the incompletely treated patients as a reservoir for the further propagation of the disease. The plasmodia may be deep-seated in the internal organs, and not found in the peripheral circulation, but one can only determine that by aspirating, for instance, the spleen. Splenic puncture is relatively a rare procedure, and one which is not often justified. The real point I wish to make, however, is that in many of the cases of intermittent chills and fever the disease is not malaria at all; these might be the symptoms of a lot of other diseases.

Dr. B. W. Fontaine, Memphis, Tenn.: After an experience of ten years in a very malarial district it has become my rule to doubt the diagnosis of this disease, malaria, unless the parasite is demonstrated in the blood. After repeated search for the plasmodia in the blood, if I fail to find any, then I doubt the diagnosis of malaria.

Dr. J. A. Chilton, Van Buren, Mo.: My first experience with malaria was personal; I had it myself, and with ten years' experience in wrestling with this disease as a physician, I have come to have certain fixed ideas regarding it, founded on this experience. I believe that the disease becomes dormant, so to speak, and remains deep-seated in the system for months, and that it requires in many cases months to free the system from it, and to effect a certain cure. I have treated a great many patients who would obtain medicine enough to keep the chill off, and notwithstanding my advice to return for further treatment, would neglect the matter until another chill, or perhaps two, would send them back to me, usually some time for the fourteenth to the twenty-first day from the date of their first visit. I have had careless patients repeat this thing many times, thus demonstrating the necessity of continuous treatment. I wish to relate one case of interest. A young man, about 22 years old came to me for medicine to relieve his fever and headache temporarily. On inquiry and investigation I found him suffering from malarial chills, and he said that he had had them for about all his life, and almost constantly for the past two years and that he had "tried the doctors" till he was discouraged, and did not wish any treatment save to get temporary relief. This man's history, together with the clinical symptoms, were all that was necessary to establish a diagnosis. I succeeded in getting him sufficiently interested in his condition to agree to stay with the treatment for four months if necessary, which he did. After beginning treatment with quinin and other tonics as iron, etc., combined with sufficient elimination through the bowels, the man did not have another chill, and in two months the color came back to his cheeks, he regained his strength and was redeemed from the ravages of malaria; he returned to his work, that of a common laborer. This man was under constant treatment for three months. I relate this case to illustrate the necessity of constant treatment, continued for a period of months, in order to cure malaria, and my belief that the plasmodium will "hibernate," so to speak, in the spleen for a winter, and come forth in the spring hungry and "seeking whom he may devour," resulting in another attack of chills, unless the patient be given proper and continuous treatment.

Dr. T. J. Ragsdale, Lee's Summit, Mo.: I should like to relate the history of four cases of malaria seen by me 2 years ago. These patients were four young men who had been away from town but returned to it with malaria. They were treated about three weeks and the malaria disappeared. These young men were apparently well from September or October until the following April. When all four developed chills and fever again within a week or ten days of each other. After three months of appropriate treatment they were cured. In citing these cases I wish to call attention to the regularity with which they suffered relapses.

Dr. D. C. Watt, Little Rock, Ark.: I dislike to think that the feeling against the mosquito is waning; the eradication of the mosquito is possible. Those of us who live and practice in the malarial countries know perfectly well that people who are protected from the mosquito by screens, suffer less from malaria than those who are exposed to the mosquito. In the treatment of malaria I think the individual himself is very much neglected; we should treat the patient more than the disease; because if we understand the normal condition and abnormal relations, we will find that the plasmodia will not be in evidence when the condition is practically restored to the normal. In the south most of the people carry with them the plasmodia; but what I wish particularly to emphasize is that we must pay more attention to the treatment of the individual. In giving quinin, a certain amount of discretion must be used. When I am treating patients from August to October I use very little quinin excepting as a prophylactic. But in the earlier months I give full doses to effect. I am sure that quinin has been the cause of immediate death of some of my patients suffering from subacute malaria. We have to consider the matter of waste and repair. I believe that it is the patient more than the disease that should be considered.

Dr. A. H. Vandivert, St. Joseph, Mo.: The statements in regard to the diagnosis of malaria by an examination of the blood, and the finding of the plasmodia, are correct, for this is the scientific way; but in the larger percentage of the cases of malaria, the diagnosis will be made by other means than a blood examination. Frequently the diagnosis will be made on the symptomatology alone. We should be careful to differentiate between malaria, septic fevers and other forms of disease which cause periodical chills and fever. There is no doubt that the administration of quinin in proper doses, if properly assimilated, will eradicate the malarial poison. When giving quinin to the extent of ½ dram we are giving a sufficient amount to stop, temporarily at least, the malaria, or the malarial infection we come in contact with. If more than ½ dram of quinin is required it means that the quinin is not properly prepared, or that it is not the right preparation, and that the drug is not given in sufficient quantities. The question always is: Why is not the drug properly assimilated? If quinin is not taken up by the stomach, then it should be administered in some other way.

This whole question of malaria resolves itself, I believe, into the correct diagnosis by scientific means if possible, or otherwise by the clinical symptoms. Success in the treatment means the continuation of the treatment over a period of months, and looking to the proper assimilation of the agent which brings about the eradication of the malarial element from the system. This is the experience of most men who live in malarial districts and who are called on to treat this disease frequently. In my section of the country there is less malaria now than there was a few years ago; the draining of the swamps has caused a decrease in the number of cases Malaria was very prevalent before the days of the investigation of the blood for the plasmodium. We certainly have advanced very far in our knowledge of this disease.

Dr. A. Comings Griffith, Kansas City, Mo.: I want to call attention to one point brought out in the paper, the similarity of malaria and syphilis. Recently a patient was brought to me with a history of infection, with chills and fever. Examination of the blood revealed the presence of the malarial parasite. This patient, a man, was placed on quinin in small doses and the chills and fever disappeared. However, the enlargement of the spleen and liver did not disappear. The patient got along nicely, was up and about, and 6 months later had shown no recurrence of the trouble. He went south because of some specific trouble and there the specific lesion was found. The blood again was examined but no plasmodia were found. The patient had a well-marked systolic murmur and his condition pointed to chronic endocarditis. He died. At autopsy there was found that the diagnosis was a correct one, chronic infectious endocarditis. There still existed an enlargement of the spleen and the malarial parasite in the blood.

Dr. Seale Harris, Mobile, Ala.: Regarding the administration of quinin in malaria, the ordinary soft gelatin capsule is usually easily dissolved in the stomach, but to be certain of solution, it may be followed with dilute hydrochloric acid. Most patients object to taking quinin in solution. Gastric disturbances following the administration of quinin do not often occur when the doses are small, but frequently follow the large doses, i. e. fifteen grains. Dr. Chapman spoke of giving a patient 150 grains of quinin in one day. His patient did not die but I think it dangerous to give such large doses. Large doses will not cure malaria any quicker, or more certainly than will 30 grains a day in divided doses. The experiments of Rogers in the tropics proved this He gave as high as from 60 to 100 grains a day, but these large doses did not shorten the course of the disease any more than the 30 grains a day, and he found that the large doses were distinctly depressing.

Dr. Wolf mentioned a case of pneumonia supposed to result from malarial infection. Malaria may have been a complication but I do not think that the plasmodium can cause a true pneumonia. The presence of the parasite in the blood does not necessarily mean that the patient is not also suffering from other disease. Always look for something else. Dr. Bass's remarks regarding the frequent absence of the plasmodium in the peripheral circulation in chronic malaria I believe to be correct. Sometimes, however, we find the plasmodium in the blood of patients who give no history of having had chills, fever, or other acute manifestation of malaria. Dr. Pratt doubts that the malarial parasite causes neuralgia, neuritis, general paralysis and nephritis One of my colleagues Dr E D Bondurant, who is professor of neurology in the University of Alabama, has made frequent examinations of blood of patients suffering from these diseases and other nervous disorders. He states that in the majority of such patients coming from malarial districts, malaria is the causative factor and the symptoms yield to quinin. Dr. Bondurant also states that he has seen cases of the acute psychoses due to malaria. Manson has also called attention to neuralgias and neuritis of malarial origin.

With regard to the effect of malaria on the kidneys, I merely cite the articles by Marchiafava and Celli in the "Twentieth Century Practice of Medicine," edition of 1900. Many others have also called attention to the fact that malaria may cause nephritis. It is unquestionable that arteriosclerosis is much more common in malarial districts than elsewhere. I must take issue with Dr. Pratt's statement about the cases of fever that do not yield to quinin in 3 days not being malaria. Most of them are not, but some cases of malaria are very resistant to quinin. I must also differ with him in what he quoted Dr. Craig as saying. In the April *Archives of Internal Medicine*, Dr. Craig states that he found the parasite of malaria in the blood of a number of patients who had been taking quinin for varying periods of time, some of them longer than a week.

In 1903, in the *Therapeutic Gazette* I reported the case of a patient who had had quinin in solution in large doses for more than a week, yet the fever continued and crescents were *found in the blood* *Last year in this Section Dr. Darling* reported several cases in which the patients had been given 30 grains of quinin a day for from 2 to 3 weeks yet the crescent forms were not destroyed. We all must agree with Dr. Witherspoon in what he says regarding the crusade against malaria. This is certainly very important and should hold the attention of all.

In regard to my authority for the long periods of quiescence or latency in malaria, I refer to Deaderick's book on malaria. Dr. Bate also spoke of the immunity, or infrequency, of malaria in the negro race. I do not believe there is any greater fallacy with regard to the negroes than is contained in such a statement. The statistics for 1900 show that in proportion to population three times as many negroes as whites died from malaria. The negroes certainly have malaria as much as do the whites but possibly not in so severe a form. I do not believe that there is any such thing as immunity to malaria. I agree with Dr. Lemann that a blood examination, whenever possible, should be made in every case of suspected malaria; but there are thousands of physicians all over this country who do not possess a microscope and yet who in nine-tenths of the cases are able to make a correct diagnosis of malaria. This is especially true in malarial districts. However, one should bear in mind that if a patient residing in a malarial district has a chill, it is not necessarily due to malaria; it may be due to a number of other causes.

The real *and important point* which *I desire to emphasize* is this: If you do not question your diagnosis of malaria, give the patient quinin at once and keep on giving him quinin until he is radically cured. It has been proved that malaria can be absolutely eradicated from malarial localities by the use of quinin alone. Koch advanced this theory ten years ago, and his plan was carried out on some islands off the coast of Africa. In less than two years, by administering quinin the disease was practically eradicated from them. In Italy and in southern Austria the same results were obtained. The most important point to remember in prophylaxis, is to cure malarial patients. Cure them. It takes several months to do this. But if you do not cure them they will be carriers of the infection from one year to another.

Differential Diagnosis Between Lichen Planus and Syphilis—The glans, penis and vulva may be affected with lichen planus, but as this is usually associated with lichen planus in other or more typical situations, such as the forearms and legs, it seldom leads to any error in diagnosis. It must be borne in mind that syphilis may occur in a patient already suffering from psoriasis or lichen planus, and when this happens the character of the non specific eruption is modified.—C. F. Marshall, in the *Practitioner*.

DIETARY STUDIES OF UNDERNOURISHED SCHOOL CHILDREN IN NEW YORK CITY*

E. MATHER SILL, M.D.

Attending Physician at the Good Samaritan Dispensary, Children's Department; Lecturer in Diseases of Children at the New York Polyclinic Medical School and Hospital

NEW YORK

The average person selects the different food materials in the market with very little knowledge of their actual nourishment value. When the income of the family is so limited that every cent must be made to go as far as possible, which is true of the average family living in the "poor" quarters of our great cities, then it is evident that ignorance of food values must mean much unnecessary expense, and perhaps suffering to those who can ill afford it.

My previous studies of 1,200 malnourished school children and the wide-spread interest shown as a result of my article on that subject have prompted me to further and deeper studies along this line, the result of which I now lay before you.

In order to make these dietary studies I have followed the plan of Atwater, since that seems to be the most accurate. Thus careful and accurate account was kept of the kinds, amounts, composition and cost of all food materials eaten during ten days, which was the period of investigation, and to insure accuracy the period should not be less. From this the cost, nutrients, and fuel value per man per day were computed in cents, grams and calories; the composition of each material used as shown by analysis, and the amounts of the different nutritive ingredients were determined. An account was kept of all the meals taken by each member of the family, as well as visitors or boarders, should there be any during this period of investigation.

The factors used in calculating the meals consumed in these dietary studies, were those commonly recognized as being the standard and were taken from Atwater's latest work, namely:

A man at hard muscular work requires 1.2 the food of a man at moderately active work.

A man with light muscular work and a boy 15 to 16 years old require 0.9 the food of a man at moderately active work.

A man at sedentary occupation, a woman at moderately active work, a boy 13 to 14, and a girl 15 to 16 years old require 0.8 the food of a man at moderately active muscular work.

A woman at light work, a boy 12 or girl 13 to 14 years old require 0.7 the food of a man at moderately active muscular work.

A boy 10 to 11 and a girl 10 to 12 years old require 0.6 the food of a man at moderately active muscular work.

A child 6 to 9 years old requires 0.5 the food of a man at moderately active muscular work. A child 2 to 5 years old requires 0.4 the food of a man at moderately active muscular work. A child under two years old requires 0.3 the food of a man at moderately active muscular work.

It is by the use of these factors that the number of meals actually taken by each member of the family is computed in terms equivalent to the number of meals for an adult man. Thus the total number of meals taken by the family is expressed in terms of meals per man, which, being divided by the number of meals per day, which is three, the number of days for one man is obtained. The total nutrients of the food eaten divided by the equivalent number of days for one man gives the amount per man per day.

DIETARY STANDARDS

Atwater reports studies of twelve laborers' families with ordinary work in large cities in the United States, in which the averages were per man per day, protein 101 gm., fat 116 gm., carbohydrates 344 gm., with a fuel value of 2,810 calories, which is an insufficient diet, according to the standards.

In eleven poor families in New York City the averages of the food actually eaten were protein 93 gm., fat 95 gm., carbohydrates 407 gm., and fuel value 2,845 calories.

In ten Russian Jewish families in Chicago the averages were, protein 137 gm., fat 103 gm., carbohydrates 418 gm., and fuel value 3,135 calories actually taken per man per day. These are enough quotations of previous studies to make our comparison.

The dietary standards as given by Atwater, and which have been pretty generally accepted, are as follows:

A man with hard muscular work, protein 175 gm. (or 0.39 pounds) with fat and carbohydrates in sufficient amounts to produce a fuel value of 5,500 calories.

A man with moderately active muscular work, protein 125 gm. with fat and carbohydrates enough to produce a fuel value of 4,150 calories.

A man with light to moderate muscular work, protein 112 gm. (or 0.28 pounds) with fat and carbohydrates enough to produce a fuel value of 3,400 calories.

A man at "sedentary" or a woman with moderately active work, protein 100 gm. (or 0.22 pounds) with fat and carbohydrates enough to produce a fuel value of 2,700 calories.

A woman at light or moderately muscular work, or a man without muscular exercise, protein 90 gm. (or 0.20 pounds) with fat and carbohydrates enough to produce a fuel value of 2,450 calories.

The average of twenty-eight dietaries studied by me showed the following per man per day (all the families having malnourished children):

Cost 19 cents, protein 95 gm., fat 68 gm., carbohydrates 407 gm., calories 2,614. These all did active or moderately active work.

Some six of these dietaries were up to or above the recognized standards, and therefore raised the general average considerably, but most of the dietaries were considerably below the ordinary standard, few being up to 3,000 per man per day, and some as low as 1,600 calories per man per day, with corresponding low fat, proteid, and carbohydrates, thus showing the undernourished condition due to lack of proper food.

In those families whose dietaries were up to or above the standard there were always other good and sufficient reasons for the malnutrition of the children, such as close quarters, overcrowding, late hours, infrequent bathing, eating candy between meals, and tuberculous infection, or convalescence from disease; also adenoids and enlarged tonsils in some cases, or organic disease.

Dietary studies of six fairly well-to-do families, at moderately active muscular work, showed averages per man per day as follows:

Cost 35 cents, protein 149 gm., fat 115 gm., carbohydrates 569 gm., and calories 3,884. Thus it will be seen these six families had about sufficient food and a fairly nourishing diet, and the adult members were well nourished. I could attribute the malnourished condition of the children only to the fact that they ate cheap candy between meals and thereby spoiled their appetites for nourishing food, lived in crowded quarters, sat up late at night, had organic disease, or were convalescing from disease. All of these were good reasons for their condition.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

Another fact that has been most strongly impressed on my mind in making a record of each child's meals is that most of them ate very little in the way of breakfast and that the nutriment which they obtained from that meal was entirely inadequate for the demands of the growing body. The average breakfast of these children consists of tea or coffee and bread, and the consequence is that many are so hungry in school that they cannot concentrate their minds on study.

From a previous study of the meals of 210 malnourished children, I found that the following breakfasts were given.

Tea or coffee and bread....................	165
Cocoa or milk and bread....................	30
Milk or tea and egg........................	10
Coffee and oatmeal.........................	4
Nothing....................................	1

It is well known that breakfast is the important meal for the growing child.

Dr. H. M. Lechstrecker, of the New York State Board of Charities, examined 10,707 children in industrial schools of New York, with the following result: 998 had coffee or coffee and bread only for breakfast; 439 had no breakfast; 998 were anemic owing to lack of nourishment. Only 1,855, or 17.32 per cent., started the day with an adequate meal.

These studies were carried on among families of the poorer classes, living on the lower "East Side" of New York City, below Fourteenth Street, and east of Third Avenue and the Bowery. The families studied were representative of the people in this district and a large number of occupations were represented. Dietary studies were made from thirty-four families. Some were found to be shiftless and slovenly and took no interest in having a clean, comfortable home and setting an attractive table, while others, though ignorant, were willing and desirous of learning how they could improve their way of living and dietaries.

The range in total income per family was from an amount not sufficient to buy the absolute necessities of life, to an amount which should be ample for their needs and equal to that on which other families have been found to live comfortably. In no case among poorer families was there any food used which required care or work in preparing; whether this was from ignorance, lack of energy, opportunity, or convenience, it is hard to say; each cause no doubt was a factor to a certain extent, but ignorance seemed to be the principal reason.

The studies were carried on and the final results calculated according to the methods of Professor Atwater. Practically all this computing work has been done with a calculating machine, but even with this great aid the amount of detail work was considerable. The data obtained in each family studied was (1) the nationality, age, sex, occupation of each member of the family; (2) the income of the family; (3) the expenditures for rent, and food, gas, coal, etc.; (4) the kind, quantity and quality of food consumed; (5) the number of meals taken by each person present during the study. From these data, and the standard tables showing the composition and fuel value of the different food materials used, the quantities of nutrients and energy consumed per man per day were computed.

This made it possible to compare results with recognized standards and to judge whether the families were receiving proper nourishment, and whether they used good judgment and intelligence in the selection and purchase of food, and also to point out how a more nutritious diet in many cases could be purchased for the same amount of money or as nourishing a diet for less money.

In thirty-four such dietary studies made, twenty-eight dietaries were found to be deficient in protein, fat, and carbohydrates, with a corresponding low fuel value per man per day, and by multiplying these results by the factor used according to the ages of the undernourished child we obtain a diet correspondingly low for it.

The average of thirty-eight dietary studies of fairly well nourished families made in the United States of persons at moderate work, showed that these persons received 134 gm. of fat, 487 gm. of carbohydrates, in combination with 102 gm. of protein.

But the average of twenty-eight dietary studies that I have made gave protein 95 gm., fat 68 gm., carbohydrates 407 gm., thus showing great deficiency in all the food ingredients.

The average of these thirty-four dietary studies showed that 61 per cent. of the money spent was for animal foods, and 39 per cent. for vegetable foods, and about the same amount of protein was obtained from the animal as from the vegetable foods (slightly more from the vegetable foods. About five times as much fat was obtained from the animal as from the vegetable foods, or over 80 per cent. Over 70 per cent. of the carbohydrates came from the vegetable foods and more than twice the number of calories were obtained from the vegetable food as from the animal food. The carbohydrates furnished by the animal food came mostly from the milk.

In the studies of nearly 200 dietaries in families of widely varying circumstances in different parts of the country, it was found that the various animal foods made up about one-fifth of the total amount of food, and furnished more than six-tenths of the protein and nine-tenths of the fat used. My studies would indicate then that these thirty-four families with undernourished children got less than five-tenths of their protein from animal food and eight-tenths of their fat from the same source.

The fuel value of each food used in these dietaries was computed by means of values previously obtained from the studies of Professor Atwater, and others, by the use of the bomb and respiration calorimeters, which give for our common foodstuffs as ordinarily used in diets, the following general estimates for the energy furnished to the body by 1 gm. or 1 pound of each of the different classes of nutrients (calling an avoirdupois pound equal to 450 gm.); to be mathematically exact it should be 453.7 gm. to the pound. Protein, fuel value, 4 calories per gram, or 1,820 calories per pound. Fats, fuel value 9 calories per gram or 4,040 calories per pound. Carbohydrates fuel value, 4 calories per gram, or 1,820 calories per pound.

Thus it will be seen, having this data and the percentage of fat, protein and carbohydrates in each article of food as per analysis,[1] in order to ascertain the number of grams of protein, fat, and carbohydrates in each variety of food, one should find first the total number of grams weight by multiplying the weight of food by 450, the number of grams per pound avoirdupois, and multiply this result by the per cent. of protein, fat, and carbohydrates as shown by chemical analysis to be present in each article.

---

[1] Atwater, W. O.: Principles of Nutrition and Nutritive Value of Food, Farmer's Bull. 142, U. S. Dept. Agric., corrected to April 5, 1906.

IMPROVEMENT OF DIETARIES BY KNOWLEDGE OF FOOD VALUES AND PROPER SELECTION OF FOOD

Almost all dietaries studied could have been improved both from a nutrient and an expense standpoint. In practically all a very small amount of the cereals, such as oatmeal, hominy, corn meal, rice, cracked wheat, etc., were purchased; also a very small fraction of the diet was made up of the dried legumes (beans, peas, lentils) although more nutriment (protein) can be obtained from these (properly cooked) for a given sum of money than from any other foods. It is well known that protein is the most important ingredient of food as it is the tissue builder, since it is the basis of muscle, bone and almost all the tissues and fluids of the body, hence its importance to the growing child. The cost of dried beans was 6 cents a pound and the cost of cereals by bulk the same.

The bulk of the nourishment in these diets was obtained from meat, milk, and bread and rolls. Baker's bread was used almost entirely, and the rolls used were purchased from the baker. This bread was rye and varied in price in the different families from 1.3 cents to 4 cents per pound and the rolls were made of white flour and were more expensive, costing about three times as much per pound as the bread. The majority of families paid from 3 to 3½ cents per pound for their bread. Those that paid less got stale bread, which is just as nutritious and healthful, and much more economical.

There is no doubt that it would have been better economy had they bought the flour and made their own bread at home if it could have been baked while the fire was being used for cooking other things, so that there would be no waste of fuel.

The milk used cost from 5 to 9 cents a quart, the cheaper grade being obtained from the groceries from the can in bulk, while the more expensive grade was delivered at the house in sealed quart bottles. For many of the poorer families more nourishment could have been obtained for the same amount of money by the purchase of skimmed milk.

The meat used by practically all the families was chuck and flank of beef, which cost them 16 to 18 cents a pound, and this was about as economical fresh meat as they could have purchased for its nutrient value; corned beef, however, might have been used part of the time to advantage with less cost.

Some of those in better circumstances bought round steak, and chicken, the chicken being an extremely expensive article of diet, for its food value, as it was purchased in small quantities, a small portion of a chicken such as a quarter at a time, which cost them anywhere from 15 to 28 cents a pound. Nearly all used fish in moderate quantities, principally carp, pike, buffalo fish, and salt herring.

One family received the same number of grams of protein, but six times as many grams of fat, and nearly as many calories from 2 pounds of herring at 15 cents as from 4 pounds of carp at 40 cents. Comparatively few eggs were used during the time of year these dietary studies were made, which was February, March and April, and those used cost from 36 to 40 cents a dozen, which made them an expensive food.

A few families bought a quart of strawberries every day at 10 cents, while others spent considerable for mineral water, and alcoholic drinks, all of which had very little food value, and were more or less injurious to health.

THE NEED OF MORE THOROUGH INSTRUCTION IN THE SCHOOLS

It is most important that the coming generation of young girls should be thoroughly educated as to the comparative nutritive value of the different foods; how these foods may be best cooked to make them nourishing and appetizing and the proper dietaries for different ages and occupations. This branch of their education has been heretofore much neglected and holds only an inferior place in their school curriculum. As the ultimate vocation of practically all is motherhood, it is far more important that they be educated in branches which will always be of value to them than that their minds be filled with languages and higher mathematics. The same girls who are now being educated will be future wives, mothers and housekeepers, and the knowledge gained in these matters will not only be of inestimable value to them in their families, in the economical purchase and cooking of food, and proper feeding of their children so that they will develop into strong and healthy men and women, but by their examples and modes of living they will educate their offspring along these lines of better living and gradually improve the nation.

It is well known that insufficient and poorly cooked food, coupled with meals uninvitingly and unattractively served, are the forerunners of alcoholism, drunkenness, crime and disease. Of 101 malnourished school children tested 55 per cent. gave a positive reaction to the von Pirquet tuberculin test.

By keeping our citizens and their children well nourished much will be done toward preventing the spread and ravages of the great white plague. The best way of accomplishing this, then, is by educating the children along these lines in the public schools. A more systematic study should be made of all the foods used as to their composition, best methods of cooking, amounts necessary and kinds best suited to different ages and occupations, and especially as to the importance of a well-cooked, wholesome and nourishing diet for the growing child. This should be gone into very thoroughly in the schools and more hours given to this most important branch.

Improvement must begin physically before any marked improvement can be made mentally, morally or spiritually, and physical development depends on the right nutrition of the body. There should be cooking classes conducted by competent cooks and teachers thoroughly trained and educated in cooking, food values, dietetics, economics, etc.

Dietaries for families with different incomes should be made out and the children taught to cook the articles suggested so that those with a limited income, as well as those better off, may be able intelligently to provide nourishing and appetizing food. It should not be lost sight of that some variety in the diet is important as thereby the stimulation of the appetite and the esthetic taste is increased, although great variety and choice of things out of season are not essential, which should be borne in mind when strict economy must be practiced.

No girl should be entitled to a graduation certificate or working papers until she has passed a rigid examination covering these subjects; and boys should be taught also the different ingredients of foods, and which foods are most healthful, nourishing and economical to buy, as well as the amount of protein, fat, and carbohydrates and number of calories necessary for proper nourishment at the different ages and in different occupations, the balanced diet and how best to obtain it. Children and adults alike should be taught that "the most healthful food is that which is best fitted to the uses."

"The cheapest food is that which furnishes the largest amount of nutriment at the least cost, and the best food is that which is both healthful and cheapest" (Atwater).

INSTRUCTION FOR MOTHERS

Passing from the education of the children we come to the immediate needs of providing a suitable, nourishing, and appetizing diet for the families. To accomplish this we must educate the mothers (for they purchase and cook the food for the family) along the same lines as those advocated in the schools. Something can be done by means of free lectures, free cooking classes, the distribution of pamphlets and other literature printed in different languages, setting forth in simple language the best, most nourishing, and most economical foods to purchase, and how to cook and serve these simple wholesome foods to make them inviting and appetizing, so that a small expenditure may return an ample nutriment value.

It is my belief, however, that only a small number of the poor and ignorant can be educated by these means; they must be reached in other ways; as, for instance, through large organizations such as the Woman's Christian Temperance Union, the Salvation Army, the American Federation of Labor, the Young Men's Christian Association, and others equally far-reaching. The United States government, and the press, through the large daily papers and other widely read, publications can most effectually reach the masses, since conditions found in New York City obtain in other large cities of America as well. A series of short articles should be written, setting forth in simple language proper diets, foods, proper methods of cooking, proper nutrition and the laws of growth, so that every wife, mother, and housekeeper might know and understand. There should be shown the high nutritive value of the cheaper foods as compared with those more costly, and methods of improved cooking. A great deal of food is badly cooked. If the cheaper foods well cooked replace the dearer kinds badly cooked, and the table be made attractive, there will result both saving in expense and happier and more contented home life. A great deal can be done in this respect by individual and group talks to mothers and children in the dispensaries, giving reasons for the foods and diets advocated. This method I have pursued for many years with most gratifying results.

REQUIREMENTS OF THE GROWING CHILD

For the proper development and growth of a child, Nature demands that certain fixed and unchangeable rules be followed and when these rules are disobeyed development and growth are impaired and often, as a result, disease follows.

A child is a young animal and should be considered as such, and should at least have as much care and attention shown it as is given to our young animals. Thousands, however, do not receive that care and attention on account of ignorance and neglect on the part of their parent.

Every child, to grow steadily in both mind and body and to be healthy must have nourishing, well-cooked food, suitable for its age and in sufficient quantities, given at regular intervals. Children are so active, and use up so much food in the shape of energy in that way, besides the food they need to develop the body and renew the wear and tear of the body, that they require a highly nutritious diet, containing a high percentage of protein, and this is especially important where the child is malnourished.

A child requires long and regular hours of sleep, and under the age of 12 years every child should be in bed at 7 or 8 p. m. Children under 7 or 8 years, especially if undernourished, should have a nap of an hour or two during the middle of the day. In my studies of over 210 malnourished school children under 10 years of age nearly 80 per cent. went to bed at 9 o'clock or later and the other 20 per cent. went to bed at 8 o'clock. The growing child to be well must be properly clothed, and have plenty of fresh air. Four or five hours out of doors every day are essential, and the sleeping rooms must be well ventilated at night.

Every normal child should have certain hours for play and certain hours for study. Long hours in ill-ventilated school rooms for young children do great harm by undermining the health of the child, which is far more important than the learning he gets. Cleanliness is an important factor in the well being and health of every child, and a tub bath should be given at least once a week in winter and oftener in summer.

If children are given a fair chance by adhering to these principles and giving them only what every child in the land has a right to demand, they will he hardy and strong and grow like little animals.

IMPROPER AND UNSCIENTIFIC FEEDING DIRECTLY AND INDIRECTLY THE CAUSE OF MANY AILMENTS

That improper and unscientific feeding of children from the time of birth to maturity is one of the most fruitful causes, both directly and indirectly, of disease, disability, incapacity for work, both mental and physical, loss of energy, susceptibility to contract and inability to withstand disease, everyone who has had wide experience must admit. This paper, however, deals with the child after the stage of babyhood has passed; in other words, the school child, up to the age of 10 or 12 years.

My experience has been in treating hundreds of these children that they contract disease much more easily and have less power of resistance than well-nourished children, and when disease is contracted it is apt to be more severe and prolonged. These children have so little reserve force to fall back on that when they have to undergo a severe illness, or operation, they are apt to succumb.

Ill-nourished children are especially subject to catarrhal affections of the nose and throat and to bronchitis; they also are very susceptible to cold, and easily affected by it. Many are affected with or subject to rheumatism, articular and muscular, and rheumatic sore throat; also not a few have chorea and rheumatic endocarditis.

All of these children are easily fatigued, both mentally and physically and have not the capacity for work that we see in well nourished children. Many of them have a tired, worn, inattentive look, complain of feeling tired and cannot concentrate their attention for any length of time, and their gaze is constantly wandering. They are anemic; their brains, as well as their bodies, are starved for want of nourishment. Many of them are put down in the schools as dullards, or backward children. In these cases good nourishing food is far more necessary for the stomach than books to feed the mind. It is an impossibility to concentrate the mind or to study on an empty stomach or when hungry.

In England, Scotland and France, nourishing meals are given in many of the schools at slight cost. Tickets are issued which provide the children with healthful, sufficient breakfasts. These tickets are previously purchased by the parents. Many meals are given free, and no distinction is made between those who pay for their meals and those who are unable to do so. The person who distributes these meals cannot possibly know whether the tickets were paid for or whether they were a free gift to the child. It has been amply proved that this does not make either parents or children paupers, so the fear of making paupers is no argument against adopting such helpful measures in our own country.

THE GREATEST FIELD FOR THE IMPROVEMENT OF THE POOR IN GREAT CITIES IS INSTRUCTION ALONG THESE LINES

The problem of nourishment which is so vital to the poor and the children of the poor, and the condition of our future population and nation at large so dependent on the way her children are nourished, that it should receive the attention of all.

We find by our studies that many poor families spend more than they can afford for food and yet receive insufficient nourishment by reason of their ignorance of food values. Attempt will be made in a general way to show how the expense for food can be reduced and yet a nourishing and wholesome diet procured. Fewer eggs and less butter can be used and the cheaper cuts of meat purchased and the difference thus saved can be expended for corn-meal, wheat-flour, cereals in bulk, rice, oatmeal, dried beans, potatoes, dried peas, lentils, whole milk and skimmed milk.

Where the income of the family is very small, meat can be replaced to a large extent by the above-named vegetables and cereals, which are much cheaper for their nutritive value. A large variety of fresh vegetables is not necessary or essential; they contain very little protein or energy, and where cost is considered one or two cheaper vegetables are sufficient. The cheaper cuts of beef contain more protein and fat and less waste than the more expensive cuts, and these with wheat-flour, bread, oatmeal, peas, and beans furnish abundant protein very cheaply.

The cheaper cuts of pork, flour, bread, sugar, corn-meal, potatoes, and rice furnish abundant fuel and energy in a cheap form.

It has been found that the cheapest source of protein is the cereals; next comes meat; the most expensive being fresh vegetables. Fancy high-priced fruits and those out of season should not be used.

The diet, as is well known, should vary somewhat with the climate and season of the year, and proper cooking of food is most important, making it more appetizing, more digestible, and more nourishing.

In the majority of families among the poorer classes the food is poorly chosen, poorly cooked and poorly served, and in not a few families there is considerable waste, especially among those who are fairly well to do.

A carefully selected diet is necessary to keep the balance so that there may be as nearly as possible the right amount of fat, protein, or carbohydrates. Extremes of diet should be avoided, and a mixed balanced diet of protein, carbohydrates, and fat maintained.

Emphasis should be laid on the necessity of setting a clean attractive table, having the meals eaten at regular hours, the whole family sitting down at the table together when the meal is warm.

If such standards can be thoroughly instilled into the minds of our poor people, more will have been accomplished toward the improvement of the present condition of the poor, and the betterment and proper and normal development of their children, and the laying of the foundation for future better living, growth, and well being, than by any other means. Indeed, along these lines is the greatest field for improvement of the poor in our great cities, and philanthropic movements should be directed towards this end.

Only those who see and treat thousands of these little undernourished, half-starved sufferers, as I do each year, can realize the appalling numbers, with their pitiful, emaciated, hungry faces, and no one but he who has become callous from many such sights, constantly working among them, can look on this tragical scene unmoved.

142 West Seventy-Eighth Street.

ABSTRACT OF DISCUSSION

Dr. William H. Welch, Baltimore: Dr. Sill has undoubtedly touched on the fundamental points. Those interested in the playground question in this country could render great aid in spreading information in regard to the matter of the food the child receives in its home. Dr. Sill spoke of the movement to furnish one meal, at least, in the schools, but objections have been urged to that on sociologic grounds. There is just one other point I want to mention, and that is the question of skim-milk. There is no question of the value of skim-milk, but the regulation of the sale of skim-milk is somewhat of a problem to the health officer. We cannot permit the sale of skim-milk when it is likely to be mistaken by the purchaser for full milk. That was brought up by the Maryland State Board of Health. They showed me packages of full milk and packages of skim milk of the same size and the same colored label, which could not possibly be distinguished, except that one was marked, "skim milk." That won't do at all. The sale of skim milk cannot be permitted under such conditions. The packages should be different or so labeled that there cannot be any possibility of mistake between the skim milk and the full milk.

Dr. N. R. Coleman, Columbus, Ohio: I must refer to the matter of giving children coffee. I cannot imagine anything more injurious for a child than to give it an article that will stimulate the vasomotor nerves, contract the blood-vessels and cut off nutrition, particularly the nutrition of the brain, that develops more rapidly than any other part of the body. I do not think any more deleterious habit could be practiced. It should be prohibited by law. Coffee, tea and cocoa, in my opinion, all have the same physiologic effect, but vary in degree. They should be spoken of in such a way, not only in this organization, but by the family physician, as to prevent, so far as possible, their use. Thirty years ago I called attention to this matter, and I have been preaching it ever since.

Dr. C. F. Wahrer, Fort Madison, Ia.: There are three great faults of diet: eating too much, not eating enough and eating the wrong kind of food. Over the first two we have not much control, but the physician does have some control over the third. An excellent wave of reform is going over the land in regard to the teaching of girls in the classes of domestic economy, the proper foods and the proper way to prepare them. The physician does not realize the importance of giving out an outline of what to eat. I have a patient whom I have been treating six years for nephritis, and though she is four years overdue in heaven, she is still alive. I have another one, a man who came to me for nose-bleed due to acute nephritis, and by regulating his diet he has not had another attack of nose-bleed. Another patient whom I had was a man who was asthmatic and could not go into a hay-field. It was all due to the horrible coffee he had been drinking. This man had been drinking coffee made by his wife, who never emptied the pot from one day to another, simply adding a little more coffee each time and letting it stand on the back of the stove to boil indefinitely. Her other cooking was equally skilful. I taught this woman how to make coffee, and her husband can now go into the hay-field without any difficulty. When a patient is told by a physician that he must diet, he goes on the theory that he must starve himself. The doctor does not tell him what to eat and what not to eat. And here we err. There are plenty of good books on the market on dietetics. Buy them, inform yourselves, then give your patients definite rules as to what to eat and what to avoid.

DR. C. G. KERLEY, New York: Those of us who have seen much of life among the poor people in any large city will understand the truth of Dr. Sill's statement regarding their ignorance. I have been in dispensary and hospital work for twenty-two years, and I am impressed with the fact that it is not that these people have not enough money, but that they have no idea of what constitutes nutritious food; and children are not fed with the idea of body-building, but merely of satisfying the appetite. The mothers are not lazy, they are untaught, and that is why they adopt a makeshift diet and do the thing that is easiest. If the physician takes the trouble to tell the mother what to do she does it. It is the primary function of the physician to instruct people how to live. That may be done through organizations of different kinds. At present there is an organization in New York City which will give a "child-welfare exhibit" in November. This exhibit will show educated people the conditions that exist among the poor, and it will be made attractive by object lessons and demonstrations in order to draw the poor and show them the results which may be achieved by right living. By that exhibit a great deal will be accomplished. It will inform the best class of people how the others live and let the ignorant be taught what constitutes proper living.

DR. S. W. KELLEY, Cleveland: Just a word or two on the subject of meals, etc., for the child in school. The plan has, of course, its different sides, the question of pauperizing, and all that. We began with free schools and then free books, in some places free shoes, then free meals, free doctors, free nurses, free dentists, and nearly every possible necessity for the child in school, until the tendency is to take the child out of the parents' hands too much and leave the parents nothing to do but to bring the child into the world and turn it over to the State for its maintenance as well as for its education.

I hope that this work as it is now carried on is only a transitional stage, made necessary by the influx of ignorant and careless parents. I do not believe in letting the child suffer in the meantime. It must not be allowed to starve or to go unclothed while getting its education, but the parents must be educated in their duty as parents, and the coming generation of parents must be better informed and more attentive in their duties as parents. I believe that ultimately the duty of school boards will be confined to education. I think that they are outside of their proper function in furnishing physicians, nurses, dentists and food to school children. That, if temporarily necessary, can be carried on by other organizations. Of course, I believe in medical inspection, but school boards should confine themselves to education, even if that includes the education of the parents in many ways. The school authorities can call to their aid and cooperation other authorities and organizations, such as the juvenile courts, the humane societies and the visiting nurses associations. For instance, in the matter of meals the social settlement workers can see that the child gets well-prepared meals at home. In illness or malnutrition the physicians can instruct nurses and the nurses working among the people can carry out these instructions.

DR. CHARLES A. CATTERMOLE, Boulder, Colo.: I want to explain a plan that is followed in the West. Dietetic errors are not so common in the West as among the people of the cities. The method we have adopted is to teach the girls in the high school the method of preparing food. They are taught cooking and buying of food in the market, and they cook and serve it in a proper way and get up a meal for the school board or a committee. In the cities children live on candies and prepared foods or go without breakfast.

MINERS' CONSUMPTION

OTTO V. HUFFMAN, M.D.
Medical Director of Children's Department, Miami Valley Hospital, and Physician-in-Chief to Fruit and Flower Mission, Children's Clinic, at Dayton, Ohio
CINCINNATI

Miners' consumption is a term used by miners to designate emaciation associated with anemia, general weakness, shortness of breath and occasionally palpitation. It is distinctly a layman's term for a general condition which may be due to a variety of causes. Whoever has observed a large number of miners must have been struck with the fact that the majority are pale and thin, and that they present the facies of chronic dyspepsia. A low state of health among miners is so prevalent and the use of the term "miners' consumption" so general that the subject merits the serious attention of the medical profession.

One does not have to look far for causes of ill health among the miners. Most mines and mining towns are without any sanitary measures whatsoever. In the mine urine and feces are disposed of promiscuously. The miner's home is situated anywhere. The outhouse is nearly always on the hillside above the home, and of course the well below. The women and children seem to thrive regardless of filthy practices, however, so we must look into the mine where the miner works for the direct cause of his condition.

According to the returns of the Twelfth Census there were 528,822 persons in continental United States reported as "miners" in the year 1900. Of this number 344,205 were reported as coal-miners; 52,024 as gold-miners and silver-miners, and 132,593 as miners not specified.

Analyses reported by the Technological Division of the U. S. Geological Survey show that the atmosphere at the face of the coal in the mine contains nearly always traces of ethane, methane and carbon monoxid gases. In the ordinary management of a mine means are taken to detect these gases before they are present in such a dangerous degree as to become inflammable. Efficient forced ventilation will usually remove the gases in sufficient quantity to minimize the danger of an explosion, but at the face of the coal where the miner is working, there will always be traces of the above-mentioned gases. The stronger the ventilation, the greater the tendency to exhaust in the rooms and blind entries, with greater liberation of gases from the newly made cuts, boreholes, and broken coal. In just what way the deleterious effects of ethane and methane are brought about when inhaled in small quantities over a long period we are not prepared to say, but we do know that carbon monoxid has the property of uniting with the hemoglobin of the red blood-corpuscles to form a rather stable compound, and that it is not readily replaced by oxygen.

In mines where dynamite and other nitroglycerin explosives are used we have another source of poison. In such explosives the nitroglycerin is mixed with inert matter. As a result of an explosion the inert matter is blown into the ore or coal. Adhering to the particles of this inert matter are small amounts of nitroglycerin which have been disseminated without entering into the detonation—being firmly fixed to the particles of the menstruum like so many tablets of nitroglycerin. Later this dust containing small amounts of nitroglycerin is inhaled during loading or shoveling, and, as every physician knows, the most efficacious way of administering nitroglycerin is to dissolve the triturate in the mouth. Another way of absorbing this poison is through the skin. Hence, these miners complain of headache, palpitation and nausea. Sometimes the men working on the tipple out in the open complain, too, as they breathe this dust when the cars or wagons are dumped.

During the past year Congress passed a law establishing a Bureau of Mines on account of the great number of miners killed or maimed annually as a result of a lack of safety devices. It may be opportune for the physicians to make some effort to better the condition of the miner from a hygienic and sanitary standpoint.

If in one of our naval ships we did not have elaborate systems of ventilation and did not make careful tests for the least increase in carbon dioxid gas for the several hundred men confined below—if we did not prohibit promiscuous expectorating, urinating and defecating, what a deplorable ship and state of health we should have!

It is no less important to have a clean, well-ventilated mine for the several hundred men working in it. The mere fact that the filth is hidden in darkness is no excuse for permitting a lack of sanitary precautions which we would not countenance one moment in the open light. We should provide our mines with better ventilation and more experts capable of analyzing the air.

Physicians in mining towns are without authority. It seems as though it might come within the province of this new bureau to make rules in regard to sanitary measures outside the mine as well as inside. Without chronic gas poisoning, typhoid, tuberculosis, hookworm, chronic nitroglycerin poisoning, and other preventable diseases, as well as fleas and chiggers, perhaps there would be no "miners' consumption."

Some physicians jump to the conclusion that the miner has general pulmonary fibrosis (anthracosis). As a matter of fact, the miner of to-day inhales very little dust, much less than the coal-handlers outside inhale, and he does not have evidences of catarrhal inflammation of the respiratory tract to the same degree as the men working in coal dust, who undoubtedly have anthracosis.

Other physicians account for the miner's pallor by the lack of sunshine, without considering real anemia. Many men have continued to work in dark but well-ventilated places other than mines for many years without developing anemia or marked pallor.

It is our duty to conduct some serious investigations in regard to the health of our miners. We should have more data at hand obtained from blood-examinations, post-mortem examinations, air analyses and other examinations which may give us exact information.

FATAL GUNSHOT WOUND

A. F. Johnson, M.D., Gresham, Neb.

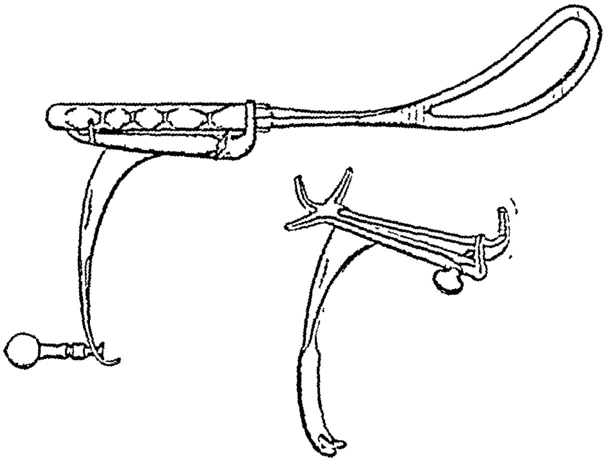
Oct. 21, 1910, I was called to see a boy about 10 years of age, who had been accidentally shot by a .44 caliber rifle, in the hands of a younger brother. The bullet entered the knee-joint from the anterior side, just internal to the patella, and passed completely through the joint, severing the popliteal artery. I arrived about ten minutes after the accident had occurred, but the loss of blood was so great, that the patient lived but a few minutes, never having regained consciousness. This emphasizes the necessity of instruction in the public schools regarding "first aid to the injured."

AXIS TRACTION HANDLE FOR OBSTETRIC FORCEPS

W. P. MEGRAIL, M.D.
WHEELING, W. VA.

The illustration shows a handle that can be readily and quickly attached to any obstetric forceps thereby making the latter a complete axis traction forceps, possessing the following advantages:

1. It is light, simple in construction, having only three parts, and very easy to apply to any forceps handle when axis traction is required.



Axis traction forceps. The figure at the top shows the handle attached to the ordinary obstetric forceps. Below on the right is a view of the handle detached.

2. It prevents the lock of the forceps from slipping and at the same time does not hinder the forceps blades from being opened or closed at the wish of the operator.
3. The handle alone is sufficient for most of the axis traction cases, but when a great amount of traction is required a "T" or cross-bar can be attached through the slot in the lower end of handle, making a larger grip.
4. This handle with the ordinary forceps that is found in the obstetric bag of every physician will prepare him successfully to terminate cases demanding a high forceps operation.

WARNING AGAINST THE INDIA-INK METHOD FOR THE SPIROCHÆTA PALLIDA*

JOSEPH H. BARACH, M.D.
PITTSBURG

Since recognition of the *Spirochæta pallida* as the probable cause of syphilis, now five and a half years ago, the staining methods, as has been said, are almost as numerous as the investigators who have studied it. Out of the many, there is one which has of late been especially prominent. I refer to the India-ink method first recommended by Burri,[1] and since by a number of other investigators.

This method, which consists in mixing the serum with diluted India ink on a glass slide and allowing it to dry in the air, is so easily carried out and requires so little technic, that its use, sooner or later, would have become quite universal. Recently, I used this method on a number of occasions, and I desire to relate my experience with it.

---

* Presented at the clinical and pathologic meeting of the Allegheny County Medical Society, Oct. 18, 1910.

[1] Burri: Deutsch. med. Wchnschr., 1910, No. 38, p. 1762.

In one patient who had a typical case of syphilis, I found true spirochetes with the India-ink stain immediately. In another case, I saw the spirochetes first with the illuminated dark field and then with India ink. In neither of these specimens did I have occasion to make a prolonged search. My third use of this stain was in the case of an adult who presented an atypical case of varicella.

The diagnosis was later verified by Dr. B. A. Booth, physician to the Contagious Hospital.

Because of the possibility of syphilis in this case, I had taken a drop of serum from a vesicle and mixed it with India ink for examination. To my surprise I saw at first sight what I supposed were spirochetes. Closer scrutiny of these objects, however, made it dubious as to their actually being spirochetes. It then occurred to me that whatever they might be, before supposing them to have come from the serum of the vesicle, it would be well to examine the pure ink. This I did and was chagrined to find that the same wavy fibers were present.

I exhibited the pure ink specimens to a number of laboratory workers, and all agreed that the non-critical and inexperienced observer might easily mistake these for spirochetes.

The ink used was Higgins' India ink, which is said to have the largest sale, and therefore would be the most likely one offered to buyers. Since then Dr. George A. Holliday, who is especially interested in this subject, and I, have examined all the obtainable inks that are sold as India ink and the results are here given.

Description.—The figures seen in the dark granular field of the India ink specimens correspond in appearance to spirochetes, bacilli, cocci and streptococci. Some fields, especially in the Higgins ink, were literally filled with these bodies, and even if *Spirochætæ pallidæ* had been present, it would have been difficult to distinguish them. In most of the fibers the undulations are not large; some, however, especially in the darker fields in which the light refraction is greater, appear characteristic enough to be deceiving.

Inks Examined.—Higgins' Black India Ink: Three bottles all show long and short wavy fibers, and straight fibers resembling coarse bacilli; also structures resembling coarse streptococci.

Higgins' Violet Ink: Unsatisfactory. The ground is not sufficiently dark.

Higgins' Red Ink: Also unsatisfactory.

Hine (Paris) India Ink: In the dark areas of the field, the ink seems to crack as enameled surfaces do; and these cracks which appear as glistening wavy fibers against the black background may prove to be misleading. This ink contained no actual fibers.

Kallos' Indelible Drawing Ink: This is offered as an India ink although it is not a true India ink. In this I found streptococcus-like structures which at times appeared as wavy spirilla.

Collins' India Ink: This shows innumerable straight and wavy figures against the dark background that could be misleading.

Gunther: Wagner's India ink contains wavy fibers, some of which in length, diameter and undulations, bear a close resemblance to *Spirochæta pallida.*

A culture of Higgins' India ink on Loeffler's blood-mixture at the end of seventy-two hours was negative.

Since the accurate determination of the presence of *Spirochæta pallida* is at present already often complicated by the presence of *Spirochæta refringens*, to use the India inks would be to add one more source of error. The spirochete-like objects seen with these inks seem capable of assuming various shapes and sizes and while most of them, by the experienced microscopists, would not receive very serious consideration, some of the specimens that I have come across at a magnification of 1,300 diameters and higher, could delude even the expert.

I know a number of men who have occasion to diagnose many cases of syphilis, and who have been using the India-ink method for some time. These men do not consider themselves expert microscopists and they admitted that they may have made this error.

In the past, diagnosis of this disease has been based largely on full development of the clinical symptoms, but at present it is being frequently made on finding the spirochetes. For that reason, the greatest accuracy must be exercised, and the possibilities of error should be reduced to a minimum.

In consideration of the above findings, I offer this experience as a warning against the India-ink method by the non-expert and the general practitioner to whom it has been so strongly recommended.

4502 Fifth Avenue.

Therapeutics

HYGIENE OF THE MOUTH AND TEETH

The great importance of the preservation of the teeth is now recognized by all persons of intelligence. Crowding together of the teeth in the jaw and irregularities and depressions in the individual teeth are causes of dental caries. A direct and exciting cause is the lodgment of particles of food between the teeth and in the depressions on the surfaces. These particles of food undergo fermentation, with the production of bacteria and acids which attack and destroy the enamel of the teeth and then cause caries of the body of the teeth. Not all food is equally injurious in this way. It is chiefly the carbohydrates, the starches and sugars, which undergo this acid fermentation. The proteins, on the other hand, do not undergo the same acid fermentation and, consequently, they are less injurious.

It is evident, therefore, that in order to prevent dental caries it is necessary to prevent the stagnation or lodgment of the starches and sugars of the food in the mouth, and particularly in, on, or between the teeth.

The decomposition of the food lodged in the mouth commences very quickly, and therefore the rule of thoroughly brushing the teeth after each meal should be observed by every member of every household. The best instrument for this purpose is an old-fashioned tooth-brush made of hog's bristles. The bristles should not be so stiff as to injure the gums, and yet stiff enough to thoroughly remove all foreign matter from between the teeth. Neither a wooden (the best toothpick) nor a quill toothpick, nor silk floss, nor a napkin or towel, nor a rubber tooth-brush can accomplish this purpose nearly so well as a tooth-brush of bristles.

Even with the greatest care it is extremely difficult to keep the teeth entirely clean, and the majority of people are careless in the care of their teeth. Consequently, it is of great importance to arrange the food so as to diminish the tendency to the lodgment of the starches and sugars of the food between the teeth. These deposits are often caused by eating foods in a soft, moist, and mushy condition, and especially by eating them at the end of the meal. On the other hand, there is less tendency to this stagnation of the food around the teeth if the food eaten is dry, fibrous, and coarse, so as to require prolonged mastication. Incidentally this prolonged mastication of hard foods, in children, tends to strengthen the teeth and develop the jaws, so that they become larger and broader, affording more room for and less crowding of the teeth.

Of course the question of dietetics is one which can not be settled offhand. A food which is advantageous from one point of view may be most undesirable from another. To speak concretely, and having in mind only the prevention of dental caries, the foods to be eaten not too frequently are the soft, mushy farinaceous foods (especially if loaded with sugar), and candy. Raw fruits and salads, dry toast and stale bread with butter, vegetables, if cooked so that they are dry and require chewing, fish and meats of all kinds, including poultry, are better for the teeth. Even young children, after they have commenced to cut their teeth, should be given crusts of bread, or dry toast, and later other forms of solid food, which require chewing, to take the place of milk and gruels and various mushy foods on which many children are fed far longer than is beneficial for them. Other factors concerned in the production of caries of the teeth besides inadequate cleanliness and too soft food, are the general nutrition and the character of the internal secretions, *i. e.*, the secretion of the ductless glands. The teeth need certain inorganic substances properly metabolized to keep up their perfect health and growth. If these substances, probably largely phosphates, are insufficient, the teeth tend to decay. Such an insufficiency is probably always more or less present during pregnancy.

Another frequent cause of dental caries is the improper care or lack of care which the mouth and teeth receive during acute illness. A prolonged diet containing insufficient salts is also a predisposing cause of dental decay.

It is astonishing to what a degree the mouths of many patients are neglected, a neglect which contributes, in part at least, to the accumulation of a thick, dry coating on the tongue, and the thick, sticky, offensive masses of so-called sordes on the gums and in and between the teeth. When the patient is lying in bed, is being fed chiefly on milk and soft foods, and is not allowed to talk, there is much greater need than during health of systematic care of the mouth. The nurse should attend to this, and the physician should see that this part of her work is not neglected. In fact, except when a patient is moribund, the condition of the patient's mouth is an indication of the ability of the nurse. Frequent wiping of the teeth, gums, and tongue with a piece of cotton held in a pair of forceps, and saturated with an alkaline solution, containing 20 per cent. of glycerin, will contribute greatly to the comfort and welfare of the patient.

To whatever the severe illness is due, the greater the weakness, the higher the temperature, and the more abnormal the mental condition, the greater attention the mouth requires. The mouth should be rinsed several times a day with warm water to which has been added a little common salt, tincture of myrrh, alcohol, or a little cologne water, to stimulate the secretions. When there is a tendency to bleeding from the gums or lips, they should be rubbed twice a day with a soft cloth bearing powdered boric acid. In patients who are partially unconscious, the mouth should be examined several times daily. Little ulcerations should be treated with boric acid or a saturated potassium chlorate solution, or perhaps better with swabs soaked in peroxid of hydrogen solution. Fissures at the corners of the mouth will generally heal with boric acid and glycerin, boroglycerid or a pure petroleum fat. If the patient sleeps with the mouth open and the tongue tends to become dry, it should be frequently moistened with a 20 per cent. solution of glycerin and water. A drink of water should be offered the patient at least once an hour, and if the individual can take but a sip at a time, it should be offered even more frequently, unless he is quietly sleeping. A piece of ice covered with thin linen or gauze and applied to the mouth and tongue is often grateful to the patient.

The things to be remembered in the care of the mouth and teeth may be summed up as follows:

1. Theoretically water should follow the milk of bottle-fed babes.

2. A soft cloth should be thoroughly moistened with a mild alkaline wash and frequently applied over the first little teeth of the infant.

3. No candy, or at least but little, should be given to young children, and as soon as their teeth have erupted they should have the more crunchy or granular cereals, and not so much of the soft, gelatinous cereals.

4. The teeth should be regularly cleaned by a dentist, at least once in six months.

5. All cavities, even small, should be filled, at least with temporary filling, so that the first teeth may be preserved as long as possible in order to develop the jaws properly, so that the second teeth need not be crowded.

6. The teeth of children and adults should be thoroughly brushed at least twice a day, better three times, with a proper brush, and, at least in the morning, with a tooth powder that is not too soapy, and at night with an alkaline mouth wash.

7. All persons, growing children or adults, should have all the tartar that may become deposited cleaned from their teeth once in three months, and examinations of the teeth once in six months will disclose cavities before they have become large ones.

8. If the teeth tend to degenerate and cavities quickly form, the trouble is generally with the nutrition, and the person is often deficient on bone-forming salts. Such patients should receive lime salts, phosphates, glycerophosphates, and iron.

There is such a large choice of official preparations to meet this need that there is no necessity for prescribing proprietary preparations. In fact, the number of preparations of the United States Pharmacopeia and National Formulary is too large. They may be enumerated as:

Calcii hypophosphis, dose 0.50 gram (7½ grains).

Syrupus hypophosphitum, dose 1 to 2 teaspoonfuls:

This contains calcium hypophosphite, potassium hypophosphite, sodium hypophosphite, dilute hypophosphorus acid, sugar, tincture of fresh lemon-peel and water.

Syrupus hypophosphitum compositus, dose 1 to 2 teaspoonfuls:

This contains calcium hypophosphite, potassium hypophosphite, sodium hypophosphite, ferric hypophosphite, manganese hypophosphite, quinin, strychnin, sodium citrate, dilute hypophosphorus acid, sugar and water.

Elixir calcii hypophosphitis (N. F.).
Liquor hypophosphitum (N. F.).
Liquor hypophosphitum compositus (N. F.).
Syrupus calcii hypophosphitis (N. F.).
Syrupus calcii et sodii hypophosphitum (N. F.).
Syrupus phosphatum compositus (N. F.).
Elixir glycerophosphatum (N. F.).
Elixir hypophosphitum (N. F.).

Elixir hypophosphitum cum ferro (N. F.).
Elixir sodii hypophosphitis (N. F.).
The dose of any one of these is from 1 to 2 teaspoonfuls.

The best iron preparations for this purpose are: tinctura ferri chloridi, 1 or 2 drops in a wineglass of water or fresh lemonade, three times a day, after meals; ferrum reductum, 0.05 gram (1 grain), in capsule, three times a day, after meals,; ferri oxidum saccharatum (*Eisenzucker*), tablets, each 3 grains, 1 three times a day, after meals.

If the teeth are delayed in eruption and do not grow properly in young children, the dried extract of the thymus gland is of value. One of the tablets is given three times a day; it is best taken between meals, crushed with the teeth, and swallowed with water.

If the child as a whole does not grow well, even if not a cretin or in any way like a cretin, small doses of thyroid extract (glandulæ thyroideæ siccæ) in dose of 0.03 gram (½ grain) once a day, is of value, and this dose is sufficient.

In adults when the teeth tend to disintegrate perhaps the best treatment is the elixir of glycerophosphates of lime and soda, and it is also well to administer this preparation, or something similar, one or more times a day, to a pregnant woman, at least during the last months of pregnancy.

9. The care of the mouth during severe illness should be on the lines above described.

10. The proper care of the teeth will prevent Rigg's disease, one of the most troublesome and painful things that can happen to the jaws, meaning a retraction of the gums and exposure of the dentine of the teeth; proper care will also prevent that bane of older individuals, *viz.*, pyorrhea alveolitis.

11. The treatment of pyorrhea alveolitis must be strenuous and persistent. There is no excuse for its presence, and it can be eradicated. The treatment is persistent cleanliness and antisepsis, the same as in ozena. There is no excuse to-day for the horrible stench perpetrated by patients who suffer from ozena. The same is true of the nastiness of the breath of these pyorrhea patients, to say nothing of the danger to themselves of infection from germs harbored in the mouth. The treatment is a frequent use of a mouth wash of 1 part of peroxid of hydrogen solution to 4 or 5 parts of warm water, and then the persistent use of an antiseptic alkaline mouth wash and tooth paste or tooth powder after the peroxid of hydrogen has eradicated and removed the pus.

12. Before any serious operation is done, especially about the mouth, and when there is no emergency, the teeth of the patient should be cleansed, cavities at least temporarily filled, and pyorrhea alveolitis, if present, cured, or at least properly kept in subjection.

GOOD SENSE IN PRESCRIBING

℞	Gm.		
Acetanilidi	2		(ʒss)
Caffeinæ sodio-benzoatis		30	(gr. v)
Pulveris aromatici	1		(gr. xv)

M. div. in chart. No. VI.
Sig.: As directed.

The evident object of this prescription is either as an antipyretic or an analgesic, or possibly as a remedy for headache. If to reduce temperature or as an analgesic, it has been shown that caffein does not reduce the toxicity of acetanilid, but rather adds to it. If it is desired to render acetanilid less of a cardiac depressant, an alkali like sodium bicarbonate is the drug that should be combined with it, and not caffein. Therefore, the only excuse for caffein in combination with acetanilid, phenacetin or antipyrin is when these drugs are used to stop a headache, caffein being of benefit in some headaches.

The best caffein, unless an effervescing preparation is desired, is the citrated caffein of the Pharmacopeia, caffeina citrata. This contains 50 per cent. of caffein, while the caffeinæ sodio-benzoas of the National Formulary contains about 48 per cent. of caffein. The latter is a more expensive preparation and weaker than the citrated caffein, and the dose is nearly double that of the citrated caffein. There is no difference in the activity in equivalent doses of these two preparations of caffein. The main object of all prescribers should be to use the same simple drug to meet the same specific indication; to require that the Pharmacopeia shall be small, and that every drug be assayed, pure, and absolutely up to standard. This can not be expected and can not be accomplished if the Pharmacopeia represents a large number of preparations of each individual drug.

The official aromatic powder contains cinnamon, ginger, cardamom, and nutmeg. There could be little object in putting these aromatics into a stomach when an antipyretic action is desired of acetanilid. In other words, there is positively no reason for it in this particular prescription, although the dose is so small.

The directions above do not state how frequently the acetanilid is to be administered. The dose, about 0.33 gram (5 grains) is now considered very large, and certainly should not be repeated more than once in the same twenty-four hours. Two or even one grain of acetanilid, repeated two or three times at three-hour intervals, will act as satisfactorily and is much safer than a large dose of this drug.

As life is short and the age rapid, unnecessary Latin should not be used in a prescription; we have not time to write it. If the Latin word *"divide"* is used, it must be *"divide in"* followed by the accusative, divide into. It is much better to use the imperative word *"fac"* followed by the accusative, as "mix and make" so many powders. It is entirely unnecessary to say "No." or *"in numero"*: if so many pills or powders are ordered it must of necessity be *in numero,* therefore it is unnecessary to say so. If the metric system is to be used, it is absurd to order 6, 7, 8, 11, 12, or 13. If more than 1 or 2 are required, let the number ordered be 5, 10, 15, or 20; in other words, absolutely smooth and proper exponents of the decimal system.

If a simple prescription is required as an antipyretic, the following is better:

℞	Gm.			
Acetanilidi		50	or	gr. viiss
Sodii bicarbonatis	2			gr. xxx

M. et fac chartulas 5.
Sig.: A powder, with water, once in three hours, if needed.

Or, it may be ordered as follows:

℞	Gm.			
Acetanilidi		50	or	gr. viiss
Sodii bicarbonatis	1			gr. xv

M. et fac capsulas siccas 5.
Sig.: A capsule, with water, every 3 hours, if required.

If immediate, rapid action is desired, any capsule can be uncapped just before it is taken into the mouth.

DYSPEPSIA AND THE PROPHYLAXIS OF CANCER OF THE STOMACH

The word "dyspepsia" used as a scientific term in its etymologic sense has long since been relegated to the realm of the obsolete. It is still applied occasionally, however, in a loose way to that miscellaneous aggregation of symptoms and distresses to which patients allude as "stomach trouble." It is becoming better understood from advances in the study of the chemistry of digestion and the secretions, as well as from the pathologic findings in the alimentary tract and the associated organs of digestion as revealed at operation and at autopsy, that most so-called stomach troubles have their seat or origin in the liver, the gall-bladder and ducts, the pancreas, the appendix, or in even more remote portions of the digestive tube, and that even real lesions in the stomach itself may be secondary to pathologic conditions far removed from that viscus. An understanding of this fact is important from the standpoint of prophylaxis, as well as from that of diagnosis and treatment. The futility will at once be seen of treating by measures directed to the stomach a hyperchlorhydria, for instance, that is due reflexly to a diseased appendix, or an obstruction of the pylorus due to spasm induced by a hypersecretion having its exciting cause in the gall-bladder. Gastro-enterostomies performed for the relief of such stomach conditions prove useless.

The influence of the appendix in the production of gastric disorder has been recognized and referred to in the writings of many authors. H. J. Paterson,[1] after seeing W. J. Mayo operate in two cases, removing the appendix when all the symptoms pointed to gastric or duodenal ulcer, which, however, was not present, began a study of these cases, and reports the histories of twenty-four patients operated on by him, each of whom had all the clinical symptoms of one or other of these types of ulcer. The removal of the diseased appendix in each instance relieved all the symptoms.

Fenwick[2] in a study of the clinical significance of gastric hypersecretion, states that he had noted that deaths from appendicitis occurred in patients with a peculiar type of hypersecretion, and the connection was suggested to him by Mayo. Fenwick even goes so far as to state that the character of the trouble in the appendix is indicated by the character of the gastric secretion, an active irritation being indicated by hypersecretion, while on the other hand, torsion, thickening, cystic dilatation or adhesion are followed after a time by a type of chronic gastritis characterized by flatulence, nausea, anorexia, excess of mucus and absence of free hydrochloric acid. Fenwick further says that a continuous flow of hyperacid gastric juice, reflexly produced by disease of some other organ—the appendix, pancreas, gall-bladder, tuberculosis or new growth of the cecum—always excites severe inflammation of the stomach and is liable to be followed by ulcer of that organ or the duodenum. It also sooner or later gives rise to spasm of the pylorus, causing pain and intermittent obstruction, which may lead to a diagnosis of cancer.

MacCarty[3] has studied the relation of the diseased appendix and gall-bladder to stomach trouble or dyspepsia, and finds that operations for gastric symptoms which have existed for years may reveal no lesion of the stomach other than aberrant secretion, but that one of the organs already named will be found in fault. Graham and Guthrie[4] cured eighty-nine out of 115 patients with gastric symptoms by appendectomy, and secured great or moderate improvement in twenty others. Cannon[5] by the injection of irritants into the large intestine produced retardation of the digestive juices, and Roger[6] produced erosions of the gastric mucosa by injections of beta-naphthol into the cecum.

Pilcher[7] in a study of 271 cases of achlorhydria gastrica hemorrhagica, a complex of gastric symptoms usually described as chronic gastritis, accompanied by hemorrhage, found that in 156 the onset seemed to bear an immediate and direct relation to various diseases. Thirty-eight of these followed infectious diseases, twelve accompanied circulatory disturbances, fourteen were post-operative, the operations having been done for various conditions, and twenty accompanied diseases of the ductless glands. In 100 of these patients operated on, the trouble in thirty-six was found to be due to appendicitis, in thirty-two to gall-bladder trouble, in sixteen to gall-bladder and pancreatic disease combined, in twelve to appendicitis and gall-bladder involvement combined, and in sixteen the stomach alone was found diseased. In twenty-four there was pylorospasm—in eighteen with appendicitis and in six with gall-bladder involvement.

[7] Pilcher, J. T.: The Journal A. M. A., Nov. 19, 1910, p. 1790.

In two cases ulcer of the stomach was found. Various other conditions were also present.

The achlorhydria, with its sequelæ, is attributed by Pilcher to reflex inhibition of secretion by disease elsewhere, the invasion of the stomach by bacteria, chiefly the streptococcus, producing irritation and erosion, with hemorrhage. Accompanying these erosions were found round-cell infiltration and engorgement of the capillaries.

Thus it will be seen that either hypersecretion or hyposecretion of hydrochloric acid may be due to the same remote causes in different patients, both leading to pylorospasm, irritation, erosion, infiltration and ulcer.

Finally, Wilson and MacCarty[8] have found in an examination of 230 cancers of the stomach that 71 per cent. had their origin in gastric ulcer.

If we accept the findings above noted, the conclusions to be drawn would be that dyspepsia or stomach troubles, functional or otherwise, in at least a number of instances have their origin or seat in some remote though functionally related structure or organ, reflexly producing hypersecretion or hyposecretion, with accompanying chemical or bacterial irritation, hemorrhage, ulcer and finally, perhaps, cancer; and that the treatment of stomach conditions would require a careful search for pathologic conditions in these more or less remote structures, looking to the stomach itself last, perhaps, for the original source of the trouble. Accepting the writers' premises, an important bearing of these facts would be that the prophylaxis of ulcer and cancer of the stomach would lie in the recognition and cure in their early stages of diseases of the appendix, gall-bladder and pancreas, as well as of other still more remote conditions that produce reflexly the symptoms recognized by the patient as stomach trouble or dyspepsia.

WILL THE WISCONSIN PURE FOOD LAW BE EMASCULATED?

Our readers will remember that last summer[1] their attention was called to the sane attitude of the Wisconsin health authorities on the subject of truthful labels on food products. The courts of that state have decided that the manufacturers of glucose cannot sell their product in Wisconsin under the euphemistic but misleading term, "corn syrup." To "get even" the glucose trust has boycotted that state and glucose cannot be had of the jobbing grocers of Wisconsin. These grocers, naturally, feel aggrieved and have passed resolutions against what they term an unwarranted loss of trade.

In an editorial entitled "Making Food Laws Ridiculous," *Leslie's Weekly* waxes indignant over what it calls "the foolish, restrictive legislation of Wisconsin," which requires that manufacturers shall tell the truth on the label. Says *Leslie's:*

> "It seems inconceivable that the people of Wisconsin should tolerate such an imposition. . . . We are not surprised to note that the Wisconsin press enters a bitter protest against any interference, under the guise of pure-food legislation, with the sale of wholesome and popular articles of food."

We, too, "are not surprised to note" that *Leslie's Weekly* looks on the restrictions due to requiring that the truth be told, as an "imposition." When we remember that the wide-spread fake "Viavi" was the subject of a "special article," and that the Alexander cancer cure[2] received a similar write-up in *Leslie's Weekly,* we naturally expect that publication to come to the defense of those who are attempting to discredit and destroy the pure food laws. Neither are we "surprised to note" that some Wisconsin newspapers are entering a protest! In the previous editorial we said:

> "For the past few years 'Karo'—a trade-marked name for glucose flavored with syrup—has been heavily advertised all over the country. We may now expect the advertising patronage of the glucose trust to be withdrawn from the state of Wisconsin in the hope that the newspapers of the state will bring pressure to bear on the state legislators to amend and emasculate the present law. It is to be hoped that Wisconsin newspapers in this instance will not sell their birthright of journalistic freedom for a paltry mess of advertising pottage."

The pottage will probably prove tempting in some cases, a consummation that the glucose manufacturers doubtless wish and expect. The cold facts of the case are that the profits to be made in selling glucose at real syrup prices are enormous—so great, that if no other question were involved, it would be, as the Wisconsin Supreme Court has decided, "a fraud to sell this article to the public under a name that induces the belief that it is procuring a syrup produced in the usual way . . ." These profits the glucose trust is willing to share with the newspapers through the medium of an advertising campaign, doubtless with the idea that few publications will tell unpleasant truths about the products whose advertisements they carry. It now remains to be seen whether the Wisconsin press will stand for the interests of their constituents at the expense of a loss of revenue. We are optimistic enough to believe that a state which has enacted, enforced and interpreted a statute such as the Wisconsin pure food law will not be found wanting in editors and publishers to defend it.

It is to be remembered that if the other states of the Union would insist on the Wisconsin standard of truthfulness in the labeling of food products, those manufacturers who fail to recognize honesty as a moral obligation would be brought to acknowledge it as a legal necessity.

In summing up its case against the Badger state's pure food law, *Leslie's Weekly* asks: "What's the matter with Wisconsin?" To answer this question in part, it might be said that there are three things, in particular:

---

[8] Wilson and MacCarty: Am. Jour. Med. Sc., 1909, cxxxviii, 846.

[1] The Journal A. M. A., July 2, 1910, p. 33.

[2] See editorial published in The Journal A. M. A., July 6, 1907, p. 48.

First, Wisconsin has a pure food law that is designed to protect the public; second, it has a food commissioner who believes that this law should be enforced and who enforces it, and third, it has a supreme court which interprets the law in the interests of the public instead of for the benefit of the glucose trust. For all of which the state is to be complimented, the protests of *Leslie's Weekly,* the jobbing grocers, and a venal press, to the contrary, notwithstanding. "What's the matter with Wisconsin?" Wisconsin's all right!

SAND-FLY TRANSMISSION OF PELLAGRA

On behalf of the Pellagra Investigation Committee[1] Dr Sambon recently visited the Italian provinces of Bergano, Milan, Brescia, Padova, Rome and Perugia, and reports that in no instance in which he came in contact with the disease did he find evidence that maize was a causal factor. Endemic centers have existed in these provinces for over a hundred years. It does not occur in the towns, but only in certain parts of the rural districts where a sand-fly is found. No actual parasite was discovered but the geographical distribution and general resemblance of the disease to other protozoal infections pointed strongly to this sand-fly origin. A parallelism is suggested between pellagra and yellow fever, the parasite of which has never yet been discovered, though its insect-borne nature is no longer denied.

Dr. Sambon asserts that he proved to his satisfaction, (1) that the endemic centers of pellagra in Italy have remained the same since the disease was first described; (2) that the season of recurrence of pellagra coincides with the season of the appearance of the full-fledged sand-fly, even to the extent that if the spring is early or late, the sand-fly is early or late in appearing, and pellagra cases are correspondingly early or late in their appearance; (3) that in centers of pellagra infection whole families are attacked at times simultaneously; (4) that in non-pellagrous districts the disease never spreads to others with the advent of a pellagrin from a pellagrous district; (5) that in the case of a family which has moved from a pellagrous to a non-pellagrous district, the children born in the former are pellagrins, while the children born subsequent to removal to a non-pellagrous district do not develop the disease; (6) that the disease is not hereditary, although infants a few months old may become infected, especially if taken to the fields in pellagrous districts, where their mothers work during the season when sand-flies are in evidence; (7) that pellagra is not contagious, but is transmitted to each individual by an infected sand-fly.

The evidence on which Sambon supports his views is strong, but more will be required to satisfy the profession that this covers the whole case. For example, it is necessary to know whether or not the species of sand-fly which Sambon considered the conveyor of the infection, or one closely enough allied to it to be similarly credited with carrying the disease, exists in this country; and if so, whether or not the occurrence of pellagra here corresponds with the distribution of this sand-fly.

Current Comment

CONSISTENCY

Medical journals in their attitude toward the American Medical Association's campaign in the interests of cleaner and saner drug therapy may be grouped in one of three classes: first, those whose editors and publishers are not in sympathy with the propaganda for reform and whose editorial and advertising pages show that "anything goes" in the way of proprietary medicines; second, those whose editors and publishers both are in hearty accord with the fight for cleaner therapeutics and whose pages—editorial and advertising—reflect the attitude of the men in charge; third, those whose editors favor the propaganda for reform but whose business managers or publishers will have none of it. The inconsistency of this last class of journals does more harm to the cause so half-heartedly espoused than does the frank opposition of those whose attitude is avowedly unfriendly. An example of this journalistic anomaly is described in the current issue of *Colorado Medicine*—a medical journal, by the way, whose pages are clean from cover to cover. Says the editor:

> In the October number of the *Vermont Medical Monthly,* the official organ of [but not owned by] the state society, appears the annual address of the president, Dr. Walter B. Hayden. Reviewing the progress of medicine during the past decade, he enumerates among other things the great service of the Council on Pharmacy and Chemistry in exposing fraudulent proprietary medicines, quacks and fraudulent institutions.
>
> "It is unfortunate," he says, "that a credulous public does not recognize the faker, nor realize the danger of his nostrums; it is equally unfortunate that a careless profession does not expose the faker and reveal the worthlessness of his mixtures. . . . Can we not lend a hand in this modern crusade?"
>
> Dr. Hayden, we can and will. Sir, we are with you heart and soul. The medical profession of Colorado reaches out a hand, and pats you on the back. You can count on us to the last drop of blood. If there is one thing that stirs our nature to its vasty deeps it is a gallant battle for the right. But, stay! What is this that confronts us in your advertising columns? Why, no others than our old friends, Fellows' Syrup of Hypophosphites, California Fig Syrup, Gray's Glycerin Tonic Comp., Sal Hepatica, Ergoapiol, Glycothymoline, Katharmon, Hayden's Viburnum Compound and, last of all, Pepto-Mangan (Gude). We don't mind the smell, Dr. Hayden, but it hurts our eyes. If the good old puritanical New England conscience can stand such company in its battle for the right, count us out.

Well said, and timely. Hybrids are unlovely things, even in medical journals. One can at least admire the consistency—whatever may be thought of the morals—of those journals which frankly sell both advertising and editorial pages to the proprietary interests. But those publications which are "neither fish, flesh, nor fowl nor good red herring" are apt to inspire in one a feeling far removed from confidence or respect.

RED CROSS SEALS

Three years ago, the National Association for the Study and Prevention of Tuberculosis adopted the plan of raising money by the attractive method of selling Red Cross stamps during and preceding the Christmas holidays. The plan worked out beautifully and resulted in good financial returns. It was followed again last year, and will also be used this year. On account of the occasional inadvertent use of Red Cross stamps in place of postage stamps, the name has been changed this year to Red Cross seals.[1] The Post-Office Department has given permission for their sale in all post-offices, and they may be purchased in various other public places in every state.[2] For this season the ambition of the promoters is the sale of one hundred million seals. This ought to be accomplished, and will be if the public can be aroused; it is merely a mite for the many. The good done with the money raised by this means is only one of the benefits to be gained. A no less important good result will be the calling of the attention of millions to the fact that there is a great white plague, and, moreover, that tremendous efforts are being made to get rid of it. Thus, it will not only enlist the sympathy and support of those who are already interested in the movement, but also the interest and support of those who have never given the matter any thought whatever. It will fix the attention of the whole public on the work, and from an educational viewpoint will be of immense importance. To repeat, the idea is a beautiful and a noble one, and should be encouraged. Undoubtedly physicians will realize their opportunity, and will cooperate in every way in encouraging the sale of these Red Cross seals.

EDUCATION BY PICTURES

Lantern-slides, illustrating the anatomy and life-history of the hookworm and the methods of preventing hookworm disease, have been prepared[3] by the Hygienic Laboratory of the United States Public Health and Marine-Hospital Service, to be loaned to medical societies, colleges, school-teachers' associations, women's clubs and other organizations interested in public health work. The moving-picture show, as a means of teaching the dangers of impure milk, has already been commented on.[4] The Edison Manufacturing Company, of Orange, N. J., has just announced the preparation of a new film of educational value, which has been produced in cooperation with the National Association for the Study and Prevention of Tuberculosis and the American National Red Cross. This film is entitled "The Red Cross Seal" and shows graphically the actual conditions that breed tuberculosis, the work of the district nurses, of the open-air camp, and of the Tuberculosis Association and the life of the tenement house district. The possibilities of such means of educating the public are practically unlimited. "Men are but children of a larger growth." Modern psychology has clearly demonstrated that the impression made by the picture is much more forcible and lasting than that produced by the spoken word or the printed page.

POLIOMYELITIS IN CUBA

The occurrence in 1909 of an epidemic of 140 cases of poliomyelitis in one province in Cuba, with smaller epidemics in others, has demonstrated that geographic situation is a factor of secondary importance in the distribution of the disease. In most descriptions of the affection it has been called a disease of temperate or cold climates, but the incidence of epidemics in Cuba shows that the tropics are not exempt. In a study of the epidemiology of the disease in Cuba, Lebredo and Recio[1] find that the special biologic conditions necessary for the life of the infectious agent are not modified in the tropics, and that it occurs in the same summer months as in the more northern countries, beginning in May or June, becoming intense in August and September, decreasing in October and becoming rare in November. The disease had not heretofore existed in epidemic form in Cuba, and the uniform manner of its appearance and evolution led Lebredo and Recio to conclude that all cases constituted a single epidemic group. A map of the affected district showed its special dissemination along the railroad line. In endeavoring to establish the origin of the epidemic the investigators were led to believe that since this epidemic followed so closely the extensive epidemic in the United States, in 1907 and 1908, particularly in New York City, with which port Cuba has extensive commercial and other relations, they were justified in assuming that the Cuban epidemic originated from that in the United States.

STREET ACCIDENTS IN LONDON

We in this country are reputed to hold life cheaply and to be more careless than Europeans in safeguarding life and limb in street traffic in large cities, in industrial establishments and on transportation systems. This may be true, but the fact must not be overlooked that street traffic in London, though admitted to be handled better than in any other large city, is far from being free from accidents. This is apparent from the statistical report of the London County Council. There it is stated that 17,000 persons were injured in 1908 by street accidents within the metropolitan police district, and that 326 were killed outright. Advances in civilization and multiplication of conveniences and luxuries have their accompanying penalties. Motor vehicles, including motorcycles, caused 6,300 of the accidents and 159 of the deaths, motorcycles being chargeable with two of the deaths. It will thus be seen that this country has no monopoly of reckless drivers of motor and other vehicles, and also that a certain number of accidents will inevitably happen in the crowded centers of population with their tremendous street traffic, despite the employment of almost any degree of human care and foresight.

Medical News

CALIFORNIA

Nurses Avert Panic.—The intrepidity and quick action on the part of the nurses of the Nauheim Hospital, Oakland, averted a panic, when the oil tank and water tower of the hospital were destroyed by fire recently. The patients were removed without casualty.

Hospital Association Election.—The board of directors of Santa Ana Hospital Association have organized and elected the following officers: president, Dr. Charles D. Ball; vice-president, J. M. Raugh; secretary, Dr. Howard S. Gordon, and member of the board of control, Dr. John Wehrly.

Care for Tuberculosis Patients.—A tract of 40 acres of the Tokayana ranch near Colfax has been purchased and will soon be occupied by a colony of tuberculosis patients. Forty cottages are being erected, and it is expected that 100 more will be built later on. This will be known as the Tate Colony and will be under the charge of Dr. Robert A. Peers, Colfax. ——The Supreme Court of the Independent Order of Foresters has purchased 40 acres of land in Lopez Canon near San Fernando as a site for a sanatorium for tuberculosis patients who are members of the order. It is expected the new institution will be ready for operation January 1.

Personal.—Dr. Henry D. Brusco, San Francisco, has been appointed a member of the board of health, vice Dr. Thomas B. Roche, resigned.——Dr. Oscar Stansbury, Chico, a member of the State Board of Health, has been granted a six-weeks' leave of absence, and will represent the board in making observations of the sanitary conditions in the Canal Zone and Cuba.——Dr. Charles H. Rowe has been appointed a member of the board of health of Oakland, vice Dr. Alonzo S. Larkey.——Dr. Chester W. Bryant, Redding, was seriously injured by being thrown from his carriage near Ingar recently. ——Dr. E. Jamieson, Grass Valley, announces his intention to retire.——In the case of Robert Thompson, alias James Grant, San Francisco, charged with the murder of Eva Swan by a criminal operation, the jury is said to have returned a verdict of murder in the second degree, November 4.

ILLINOIS

Personal.—Dr. William M. Harsha, Chicago, has been appointed a member of the surgical staff of St. Luke's Hospital. ——Dr. James W. DuComb, Beckemeyer, has been appointed a member of the board of pension examiners of Clinton County, vice Dr. Thomas E. Alsop, deceased.

State Board Convictions.—The secretary of the Illinois State Board of Health reports that Walter Vogel, a "chiropractor," was found guilty November 18, of practicing medicine without a license. The trial took place at Savanna before the Carroll County Circuit Court, and a fine of $200 was imposed. This is the third judgment against Vogel, making a total of $500 in fines assessed against him.——The secretary also reports the conviction on November 17, of Minnie Meyer, a fortune teller located at 2142 W. Harrison Street, Chicago, for practicing medicine without a license. This case was heard in the Municipal Court of Chicago and the evidence disclosed that the fortune teller had given medicine to women to produce abortions. The trial judge, Hon. John G. Scovel, instructed the attorney for the state board to call the attention of the state's attorney of Cook County to the evidence as submitted, as a basis for criminal prosecution.——Nathan Ginsburg, 1587 Milwaukee Avenue, Chicago, is also reported as having been convicted by a jury and fined $100 and costs, November 14, in the Municipal Court of Chicago, for practicing medicine without a license. This man took a short course at some "optical school" and received a diploma conferring on him the degree of "doctor of optics." The testimony showed that "he had administered medicine for 'nervousness' and had used a card styling himself 'Dr. M. Ginsburg, eyesight specialist and defractionist.'"

INDIANA

Prophylaxis Against Blindness.—Dr. George F. Keiper, Lafayette, chairman of the committee of the Indiana State Medical Association on Ophthalmia Neonatorum, advises that the note in The Journal, November 5, conveyed a wrong impression regarding the action of the committee. There was merely an informal meeting of three members to talk over matters that the chairman had in mind, and on which he sought advice. The committee is not yet ready to speak about the law, and will not be ready until the representatives of all schools of medicine have discussed the matter in joint meeting. The laws adopted by several states on this subject place no responsibility at all on the physician; the responsibility rests with the midwife or nurse to report to the health officer or legally qualified practitioner within six hours after a baby's eyes become sore, that the condition exists.

MARYLAND

Personal.—The Lonaconing Board of Trade has organized with Dr. James O. Bullock as president, and Dr. Henry M. Hodgson as vice-president.——Dr. Thomas W. Koon has been appointed city physician of Cumberland.

Society Meetings.—Wicomico County Medical Society, at its annual meeting, November 17, elected the following officers; president, Dr. Louis W. Morris; vice-president, Dr. J. McFadden Dick; secretary, Dr. Harry S. Wailes; treasurer, Dr. Harry C. Tull, all of Salisbury; censors, Drs. J. H. Lynch, Quantico; Harry C. Tull, Salisbury, and John M. Elderdice, Mardela Springs; delegate to the Medical and Chirurgical Faculty of Maryland, Dr. George W. Todd, Salisbury, and alternate, Dr. Lawrence C. Freeney, Pittsville.——Frederick County Medical Society has elected the following officers: president, Dr. Charles F. Goodell, Frederick; vice-presidents, Drs. Ira J. McCurdy, Frederick, and Morris A. Birely, Thurmont; secretary, Dr. Levin West, Brunswick; censor, Dr. Alvey J. Smith, Jefferson, and delegate to the State Medical Society, Dr. Thomas C. Routson, Buckeystown.

Baltimore

Personal.—Dr. Charles W. McElfresh is holding a physicians' conference at the University of Maryland Hospital every Thursday on the various aspects of diet.——Dr. J. Frederick Adams, while riding near his surburban home, was painfully injured by an accidental gunshot wound of the hip, inflicted by a careless hunter.

MICHIGAN

New Tuberculosis Infirmary.—The board of health of Grand Rapids has decided that the new diphtheria hospital shall be converted into an infirmary for the care of tuberculosis patients——The Chippewa County board of supervisors has appropriated $1,700 to establish a tuberculosis hospital.

New Harper Hospital.—Ground has been broken for the new six-story surgical building of the Harper Hospital, which is to cost $200,000 and will accommodate 200 patients. This is the first of the series of buildings of the new Harper Hospitals.

Court Decides Antituberculosis Dispute.—Judge Hosmer of the Circuit Court has decided that the incorporated society known as the Detroit Society for the Study and Prevention of Tuberculosis, must pay to the unincorporated society the $13,500 collected on "tag-day" and the books and records of the society.

Personal.—Dr. Harry W. Bradley, Saginaw, is reported to be critically ill with typhoid fever.——Dr. William S. Connery, Saginaw, coroner of Saginaw County, was thrown from his carriage, November 12, but was not seriously injured.——Dr. Oscar Le Seure, Detroit, underwent an operation at Grace Hospital, November 12.——Dr. William F. Hake, Grand Rapids, sustained painful injuries of the leg in an automobile accident, November 8.——Dr. William H. Marshall, Boyne City, has disposed of his practice and started for Europe.

The Prevalence of Small-Pox.—Serious conditions regarding small-pox appear to exist in northern Michigan, where an aggravated type of the disease is causing anxiety to the State Health Department and local health boards. As usual the unvaccinated are the sufferers. A serious outbreak of the hemorrhagic type is reported in Saginaw, where about 200 cases have thus far been reported. During October eighteen deaths occurred, and up to November 19, twenty deaths. The authorities are taking every precaution to control the disease, and at present only a few cases are developing, and these of mild type, as a result of compulsory vaccination and revaccination of the entire population, the quarantine of infected places, and the stoppage of trains at only one station in the city, where inspectors are placed to vaccinate and disinfect every individual leaving the city. A severe outbreak of the disease is reported from the Michigan Home for the Feeble Minded, Lapeer, where twenty-six cases and seven deaths have occurred. The home is strictly quarantined and a company of the National Guard of Michigan is stationed around the home to prevent the 150 employees, who are more or less panic stricken, from leaving. The condition is improving, the situation is being well-handled and no further trouble is anticipated.

Society Meetings.—At the annual meeting of the Ingham County Medical Society held in Lansing, November 8, Dr. Orrin H. Freeland, Mason, was elected president; Dr. Louis W. Toles, vice-president; and Dr. Samuel Osborn, Lansing, secretary-treasurer.——Schoolcraft County Medical Society, at its annual meeting, elected the following officers: president, Dr. Andrew Nelson, Manistique; vice-president, Dr. Samuel S. Hackwell, Blaney; and secretary-treasurer and delegate to the State Society, Dr. George M. Livingston, Manistique.——At the annual meeting of the Eaton County Medical Society, held at Charlotte, Dr. Clarence B. Wasson of Bellevue was elected president; Dr. Flavius J. Knight, Charlotte, vice-president; Dr. Arthur H. Burleson, Olivet, secretary-treasurer; and Dr. Philip H. Quick, Olivet, delegate to the State Society.——The Tri-County Medical Society, made up of physicians of Wexford, Missaukee and Kalkaska counties, organized at Cadillac, November 4, and elected the following officers: president, Dr. Victor F. Huntley, Manton; vice-president, Dr. Raphael Brodeur, Cadillac; secretary-treasurer, Dr. Wallace J. Smith, Cadillac; delegate to the State Medical Society, Dr. Sair C. Moore, Cadillac; and alternate, Dr. Wallace J. Smith, Cadillac.——Hillsdale County Medical Society, at its annual meeting held in Jonesville, elected the following officers: Dr. E. Arthur Martindale, Hillsdale, president; Dr. Malcolm Graham, Jonesville, vice-president; and Dr. Burt F. Green, Hillsdale, secretary-treasurer.

MISSOURI

Sanitary Fountains for Schools.—Fifty sanitary drinking fountains for the Springfield public schools will soon be installed.

New Building for Sanatorium.—A new building to cost $35,000 has been commenced at Mount Vernon Sanatorium for the treatment of tuberculosis.

State Conference of Charities.—The eleventh annual conference of State Charities and Corrections, in session at Chillicothe, November 10-12, decided on Kansas City as the place of meeting for next year, and elected Dr. Thomas Riley, St. Louis, president, and Dr. G. Wilse Robinson, Kansas City, vice-president.

Society Meets and Banquets.—At the annual meeting and banquet of Caldwell County Medical Society at Breckenridge, Dr. George S. Dowell, Braymer, was elected president; Dr. Oscar O. Meredith, Breckenridge, vice-president; Dr. George W. Goins, Breckenridge, secretary-treasurer (reelected), and Dr. William T. Lindley, Hamilton, delegate to the state association.

Banquet to Physician.—Dr. Thomas H. Doyle, St. Joseph, former mayor and now police commissioner, was the guest of honor at a complimentary dinner, November 7, by the St. Joseph-Buchanan-Andrew County Medical Society, the occasion being his seventieth birthday. Dr. Charles R. Woodson presided as toastmaster, and Dr. James W. Hedden, on behalf of the St. Joseph-Buchanan Andrew County Medical Society, presented Dr. Doyle with a loving cup.

Personal.—Dr. Thomas B. Holder, Ash Grove, was accidentally shot in the hip while hunting near Walnut Grove, November 9.——Dr. Walter M. Cross, Kansas City, has been reappointed city chemist.——Dr. Oliver C. Gebhart, St. Joseph, major in command of the Field Hospital Corps of the Missouri National Guard, has been detailed to inspect the medical property of the state.——Fire of unknown origin destroyed the office of Dr. William L. White, Springhill, November 1.

St. Louis

Hospital Sunday Fund.—The annual report of the St. Louis Hospital Saturday and Sunday Association shows that during the past year $46,469 was donated to the fund.

Opposes Closing of Dispensary.—Business men of South St. Louis appeared before the Hospital Board at the public hearing, November 1, and protested against the action of the board in closing the South Side Dispensary.

Hospital Staff.—The names of Drs. Bransford Lewis and Jesse S. Myer should have been given in the list of names of the Municipal Hospital staff which appeared in The Journal, November 5. Dr. George C. Crandall has been selected chairman of the visiting staff.——Dr. E. Lee Myers, senior physician of the City Hospital, has resigned.

Complete Addition to Sanatorium.—The west wing addition to the Sanatorium at the City Insane Asylum has been completed, and all insane patients housed in the infirmary have been transferred to the Sanatorium. The quarters vacated by the insane patients will be occupied by the poor patients, hitherto cared for at the Female Hospital, and the Female Hospital will be abandoned for the present.

Vaccination Resolutions.—At a special meeting, called for the purpose, October 28 and 29, the St. Louis Medical Society adopted the following resolutions:

> Whereas, There have recently appeared in several of the daily papers of this city, editorials and other articles decrying the practice of vaccination as useless, unscientific and dangerous, and
>
> Whereas, Such editorials or articles may do great harm unless promptly answered by the medical profession, therefore, be it
>
> *Resolved*, That the St. Louis Medical Society declares that vaccination, well and thoroughly done, absolutely prevents small-pox.
>
> *Resolved*, That the truth of this statement is absolutely established by facts and figures
>
> *Resolved*, That the rare accidents reported as following the procedure, however deplorable in themselves, are outweighed a hundredfold by the enormous benefits which vaccination has conferred on humanity.
>
> *Resolved*, That vaccination has, since its introduction 114 years ago, saved more lives than any other single measure known to science.
>
> *Resolved*, That the necessity of thorough vaccination of this community, and especially of its children, is as great to-day as ever.
>
> *Resolved*, That the secretary be instructed to furnish a copy of these resolutions to each of the daily papers of this city, with the request that they be published.

NEW JERSEY

New Site for Tuberculosis Hospital.—The hospital committee of the Morristown Antituberculosis Society has selected a site for its hospital property at Morris Plains. The property has been donated to the society by Frederick Burnham.

Donation to Day Camp.—David B. Mills, Montclair, has donated $800 to the Antituberculosis League of the Oranges, $500 of which is to be used for the fresh-air school, and the remainder for the maintenance of the day camp for children during the winter.

Personal.—Dr. Harry H. Sherk, Camden, was seriously injured in a collision, November 3, between his automobile and a trolley car.——Dr. Frank M. Dedaker, Philadelphia, has succeeded Dr. Harry C. Fish as resident physician at the Mercer Hospital, Trenton.——Dr. Francis K. MacMurrough, Jersey City, has moved his office to One Hundred and Forty-fifth Street and St. Nicholas Avenue, New York City.

Elect Officers.—The annual election of officers of the Washington County Medical Society resulted as follows: president, Dr. Frank P. McKinstry; vice-president, Dr. Charles M. Williams; recording secretary, Dr. Frederick J. LaRiew; corresponding secretary, Dr. Thomas S. Dedrick, all of Washington; treasurer, Dr. Edward H. Moore, Asbury; and trustees, Drs. Charles B. Smith and George C. Young, Washington, and Theodore B. Fulper, Junction.

Benefit by Open-Air Schools.—The pupils in attendance at the outdoor school opened last month by the Montclair Board of Education are already beginning to show improvement as the result of their studies in the open air. Some of the pupils have gained as much as a pound a week since the school has been in session, while only two of the twenty-two members have decreased in weight. The children who are unable to pay for transportation are furnished free transportation to the school and daily lunch is also provided.

Censure Physicians Who Leave Hospital.—The board of trustees of Mercy Hospital, Trenton, has passed resolutions holding Dr. Edward T. Craney, Philadelphia, and Harvey W. Lloyd, Shamokin, who summarily left the hospital, giving as a reason their inability to work under the superintendent, "highly censurable for their reprehensible, unprofessional and unethical conduct," and directing that the names of these individuals be entered on the minutes of the proceedings of the staff of the hospital as being recommended for dishonorable dismissal.

NEW YORK

Social Service Department Instituted.—A social service department has been instituted at the Buffalo General Hospital, in charge of Miss Lucia Stockton, who has spent several weeks in Boston becoming acquainted with the methods in use at the Massachusetts General Hospital.

Health Conference.—The tenth annual Health Conference of Sanitary Officers of the State of New York was held under the auspices of the New York State Department of Health in Buffalo, November 16 to 18. The chief subjects of discussion were "Public Health in the School," "Public Health in the Press," "The Health Department, Its Supreme Value to the People," and "Communicable Diseases." On the evening of November 17 a smoker was held at Hotel Iroquois.

New York City

Personal.—Dr. Travers R. Maxwell has been appointed assistant sanitary superintendent of Brooklyn, vice Dr. Alonzo Blauvelt.——Dr. David Edward Hoag has been elected lecturer on nervous and mental diseases in the New York Polyclinic Medical School and Hospital.

Municipal Milk Supply.—The New York Milk Committee will hold a conference December 2 and 3, to discuss more efficient ways of controlling the municipal milk supply in New York City. The work of the conference will be in four sections: "Milk Economics," "Milk Supply and Public Health," "Milk Standards," and "Milk Commissions." The meetings will be open to the public and the medical profession is invited to participate in the discussions. Information regarding the program will be furnished by Dr. Ira S. Wile, chairman of the conference committee, 230 W. 97th street.

Medical Sociology.—The preliminary announcement of the formation of the American Society of Medical Sociology has appeared. The object of the society is to study radically the questions of socio-medical nature, such as the need of a federal department of health; tuberculosis as an economic disease; whether there is any demonstrable relationship between the strain of our modern life and the increase of insanity; whether cancer is on the increase, and if so, what the probable etiologic factors are, etc. Dr. Abraham Jacobi is honorary president of the association, Dr. William J. Robinson, president, and Dr. A. C. Jacobson, secretary.

OHIO

Fraternity to Meet.—The fifteenth biennial convention of the Grand Chapter of the Nu Sigma Nu Medical Fraternity will open in Cleveland, November 26, with headquarters at the Hollenden.

District Society Meeting.—The seventh annual meeting of the Second Councilor District Medical Society was held in Springfield, October 25, and the following officers were elected: president, Dr. Charles L. Minor, Springfield; secretary, Dr. Henry D. Rinehart, Dayton; and treasurer, Dr. Pearl R. Madden, Xenia.

County Tuberculosis Sanatorium.—Plans are being prepared by the commissioners of Knox County for the construction of a building for the care and treatment of patients with tuberculosis. Under the new law, which goes into effect January 1, a separate building must be provided for tuberculosis patients at all county infirmaries.

Personal.—Dr. James R. Davis, Chardon, sailed for Europe November 2.——Dr. Sample B. McKerrihan has been appointed city physician of Portsmouth.——Dr. Frank E. Kitzmiller, Piqua, is ill at the Memorial Hospital.——Dr. James B. Ray, health officer of Portsmouth, has decided to retire from practice and will settle on his farm near Harrisonville.——Dr. Harry L. Connett, Dayton, has been appointed pathologist at the Athens State Hospital.——Dr. Noah Myers has been appointed a member of the board of health of Springfield, vice Dr. Ira E. Seward, resigned, to accept the position of health officer, made vacant by the resignation of Dr. Henry Baldwin.——Dr. William C. Gates, Bucyrus, was seriously injured in a collision between his automobile and an interurban car, November 5.——Dr. Frederick P. Minton, Toledo, who has been seriously ill with septicemia, is reported to be convalescent.——Drs. Warner Hopkins Tuckerman and William C. Tuckerman, Cleveland, have returned from abroad.

Cincinnati

Antispitting Ordinance Enforced.—During the last week twelve individuals were arrested by the sanitary police for violation of the antispitting ordinance.

Miami Alumni Meet.—At the annual meeting of the Miami Medical College Alumni Association the following officers were elected: president, Dr. William C. Harris; vice-presidents, Drs. Joseph E. Pirrung, William C. Herman, Frederick W. Lamb and Daniel J. Davies; and secretary-treasurer, Dr. C. J. Broeman.

Dandridge Memorial Meeting.—The Cincinnati Academy of Medicine devoted the evening of November 14 to a memorial to Dr. Nathaniel Pendleton Dandridge. The following addresses were made: "Dr. Dandridge as a Colleague," by Dr. Byron Stanton; "As a Friend," Dr. Dan Millikin, Hamilton; "As a Surgeon," Dr. John C. Oliver; "As an Executive," Dr. Asa B. Isham; "As a Staff Officer," Dr. B. Knox Rachford; "As a Teacher," Dr. Julius H. Eichberg, and "As an Adviser," Dr. Christian R. Holmes.

Personal.—Dr. Jacob L. Tuechter has been appointed clinic director of the Cincinnati Antituberculosis League. He began his work November 11, and is on duty every day from 12 to 2, and on Monday and Thursday evening from 7 to 8. He is assisted in his work by the following volunteer staff: Drs. William H. Strietmann, Charles E. Iliff, Arthur J. Light, Marcus E. Wilson, Oscar Berghausen, Edith Smith, J. Emmitt Fayen, Edw. D. Allgaier, John R. Meek and A. G. Huffmann.——Dr. Charles L. Bonifield has been appointed a member of the board of medical directors of the Cincinnati Hospital, vice Dr. N. Pendleton Dandridge.——Dr. Joseph W. Dodds, assistant health officer of Cincinnati, has resigned.——Dr. Edward H. Thompson, who was recently operated on for appendicitis, is reported to be convalescent.

Asks Injunction in Milk Case.—The Milk Commission of the Cincinnati Academy of Medicine is said to have filed suit in the Common Pleas Court to enjoin Charles I. West & Son from using parchment seals on their milk bottles and from advertising that they are selling certified and inspected milk. The commission claims that its object is the improvement of the milk supply in this city and that it has adopted two standards, "certified" and "inspected," which denote the amount of bacteria contained, and these labels are allowed only after the milk commission has made an inspection and passed on the condition of the dairies and cows and the method of handling milk, the expert work being in charge of the experts of the Bureau of Animal Industry of the federal Department of Agriculture. The commission claims that the defendant company has been using the labels and advertisements since October 1 last.

PENNSYLVANIA

Medical Library Started.—Dr. John S. Van Voorhis, Belle Vernon, the only living charter member of Fayette County Medical Society, has started a movement for the establishment of a society library by donating seventy volumes.

Hospital Reopened.—St. Margaret's Memorial Hospital, Pittsburg, which has been closed for several years, has been newly equipped and was opened for public inspection, October 1. The medical staff consists of Drs. Percival J. Eaton, Elwood B. Haworth, Sydney A. Chalfant, Evan W. Meredith, William C. White, William W. Blair, and William P. Barndollar.

Philadelphia

Pennsylvania Seniors to Edit a Medical Record.—The senior class of the medical department of the University of Pennsylvania will edit a medical record to be known as *Scope*.

Candy Men Attack Pure Food Statute.—Counsel representing twelve manufacturers, attacked the constitutionality of the Pennsylvania pure food act of May, 1909, in argument before Judges Buffington, Lanning and McPherson in United States Circuit Court. It was the complaint of the dairy and food commissioner Faust and his agent Harry P. Cassidy, that the defendants used sulphur dioxid. To this the candy manufacturers replied that sulphur dioxid is used in small quantities only, but is permitted in far greater quantities in molasses and dried fruits, therefore the act discriminates against the confectionery trade and is contrary to the constitution.

GENERAL NEWS

Interstate Physicians Meet.—The annual meeting of the Marinette (Wis.) and Menominee (Mich.) Medical Society was held in Marinette, November 9, and the following officers elected: president, Dr. Henry F. Schroeder; vice-president, Dr. Simon Berglund, and secretary-treasurer, Dr. Sherman E. Wright, all of Marinette.——The forty-second semiannual meeting of Union District Medical Association was held at Oxford (Ohio) Retreat, October 27. Dr. R. Harvey Cook, Oxford, was elected president, and Dr. Pearl M. Sater, Hamilton, was reelected secretary. The next meeting will be held in Richmond, Ind., in April.

Canal Zone Sanitation.—The report of the chief sanitary officer of the Isthmian Canal Zone Commission for September shows that during the month forty-eight deaths of employees occurred, thirty-three of which were from disease, and fifteen for external causes, equivalent to an annual mortality of 11.47 per 1,000. The death rates for Septembers of previous years were as follows: 1909, 12.76; 1908, 12.78; 1907, 26.83; 1906, 57.34 (in this year there was an epidemic of pneumonia among the employees); 1905, 32; and 1904, 14.31. Of the deaths from disease during the month, pneumonia caused six; malarial fever, four; pulmonary tuberculosis, three, and typhoid fever, two. No case of yellow fever, small-pox, or plague was brought to or originated on the isthmus during the month.

Hookworm Slides Available.—In a circular letter from the Hygienic Laboratory of the United States Public Health & Marine Hospital Service at Washington, Dr C W. Stiles announces that the demand for lantern slides to illustrate the anatomy and life history of the hookworm and the methods of preventing hookworm disease has increased to such an extent as to make it necessary to prepare a number of extra sets of slides These will be loaned to medical societies, colleges, teachers' associations, women's clubs and other organizations that may desire to use them on condition that all requests for their use be sent through the secretary of the state board of health and that the slides be returned express prepaid immediately following their use Preference will be shown to societies and institutions located in hookworm infected states

Surgeons Organize Congress—The Clinical Congress of the Surgeons of North America was organized at the Hotel La Salle, Chicago, November 17, the initial membership being made up of the surgeons in attendance at the series of clinics It is proposed to continue these clinical reunions year by year in one of the large cities of the country Membership is made up of surgeons who register at the regular sessions of the congress The following officers were elected president, Dr Albert J Ochsner, Chicago, vice president, Dr John G Clark, Philadelphia, editor and general secretary, Dr Franklin H Martin, Chicago, treasurer, Dr Allen B Kanavel, Chicago, and general manager, Mr A D Ballou, Chicago

Red Cross Seals—The Christmas seals of the National Association for the Study and Prevention of Tuberculosis will be on sale all over the United States in postoffices and elsewhere in a few days and throughout the holiday season We show the design of this year's seal on the left and last year's stamp on the right The actual seals are in red and green and are very attractive for fastening gifts and embellishing letters, etc The proceeds of the sale go to the above mentioned association for its work against the great white plague All possible publicity is being given to the sale, and. in many cases, physicians are taking the lead in seeing that the seals are on sale in their several communities, and that the public is informed through the local newspapers The subject is further spoken of in the Editorial Department in this issue

AMERICAN RED CROSS
MERRY CHRISTMAS HAPPY NEW YEAR

1910 Seal

1909 Stamp

Infant Mortality Prevention—The first annual meeting of the American Association for Study and Prevention of Infant Mortality took place at McCoy Hall, Johns Hopkins University, Baltimore, Nov 9-11 An exhibition was held in connection which remained open until November 16 The meeting and exhibition attracted a representative attendance of physicians, sanitarians, trained nurses and social workers from the United States and Canada Resolutions were adopted committing the association to a campaign in the interest of birth registration, encouraging the promotion of undertakings for the prevention of disease in rural communities, urging more practical instruction in the subject of hygiene in normal schools, and in other training schools for teachers, and advocating the establishment of a national department of health The subject discussed at the opening session was "The Duty of a Nation to Its Potential Citizens" Dr J H Mason Knox, Jr, President, 1909 1910, presided, and Cardinal Gibbons pronounced the invocation The speakers were M Jusserand, French Ambassador to the United States, Dr Abram Jacobi, New York, Professor Irving Fisher, of Yale University, and Dr William H Welch, of Baltimore The other sessions were presided over as follows Philanthropic Prevention Dr Hastings H Hart, of the Russell Sage Foundation, New York, Municipal, State and Federal Prevention, Dr William H Welch, Medical Prevention, Dr L Emmet Holt, New York, and Educational Prevention, Dr Helen C Putnam, of Providence The list of officers was published in THE JOURNAL of November 19, page 1819 The American Association for Study and Prevention of Infant Mortality was organized at New Haven, one year ago, following the conference called by the American Academy of Medicine on the Prevention of Infant Mortality The association closes its first year with a membership of over five hundred The enrolment is distributed throughout thirty five states Thirty two societies have entered into affiliated relations with the association The headquarters are at the Medical and Chirurgical Faculty Building, 1211 Cathedral Street, Baltimore, and Miss Gertrude B Knipp is the executive secretary.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Nov. 12, 1910

A Home Hospital

Patients who require hospital treatment in London may be divided into two classes—the poor, who are admitted into the hospitals where they are treated gratuitously, and the rich, who go into nursing homes The latter are private enterprises in which the total expenses may amount to $1,000 or $1,500 Now, there are many patients who cannot be classed as poor, but who cannot pay these charges, and these, though able and willing to pay moderate charges, are driven into the hospitals to become recipients of charity intended only for the poor A movement is now on foot in London to remedy this evil The Westminster Division of the British Medical Association proposes to build a small hospital containing forty beds, equipped in the most modern fashion to accommodate patients at a varying scale of fees There will be no regular staff but each patient will be attended by his own physician, who can call in any assistance he may require The cost of the undertaking is estimated at $60,000 The institution will be entirely controlled by physicians, with perhaps the assistance of one or two business men The scheme, if successful, will probably lead to the establishment of similar institutions throughout the country

Food Requirements

A very careful series of observations of the dietary of the Bengalis has been made by Captain D McCay of the Indian Medical Service, and is interesting in connection with the revolutionary doctrine of Professor Chittenden as to the small amount of protein necessary for man The subjects belonged to various classes, whose protein metabolism amounted to 0 113 gm of nitrogen per kilogram of body weight per day Professor Chittenden states that "a daily metabolism of 0 1 to 0 12 gm of nitrogen per kilogram of body weight is quite adequate for physiologic needs, provided a sufficient amount of non nitrogenous food is taken to meet the energy requirements of the body" In the Bengalis we have a whole race who for centuries have lived on the dietetic system advocated by the American professor Their physical development does not support his contention Captain McCay finds that the Bengali is 25 per cent lighter than the average European and has a smaller chest measurement, though of much the same stature His blood also contains 25 per cent less hemoglobin and its pressure is 25 per cent less than that of the European Compared with Anglo Indian and Eurasian students, Bengali students show no progress in physical development during their period of study between the ages of 16 and 20, though they all live in similar surroundings and differ mainly in the fact that they consume about 0 11 gm of nitrogen per kilogram of body weight less as against 0 19 of the two former classes In physical endurance and activity the Bengali laborer is much inferior to the European In Calcutta insurance offices rate all Bengali lives as five years worse than European, and one large office will accept the policies of only well educated Bengalis of the higher castes, and even then not beyond the ages of 35 to 38

Plague in England

In my last letter to THE JOURNAL [November 19, p 1820] the epizootic of plague among rats in Suffolk was reported United action is being taken by the various local health authorities around Ipswich (the capital of the county) in the destruction of rats Not only in the affected district is this being done, but precautions are being taken in the adjacent districts to prevent the spread of the disease to them The peninsula shaped district lying between the rivers Orwell and Stour, in which the disease first appeared, is being systematically scoured for rats As hares and rabbits have also been found dead from the disease, these animals and other game from the affected district are no longer being eaten Two ferrets have died from plague after eating a dead rabbit, and a warning has been issued not to feed them on rabbits Vegetable growers in the affected district are incurring serious losses, as they cannot sell their produce In London special precautions against the introduction of plague are being taken Rats dead from the disease have been found in the docks Last month 3 095 rats were destroyed in vessels and dock warehouses, making a total of 640,619 exterminated since the work of destruction was systematically begun in 1901.

The Employment of the Tuberculous

The employment of persons who have recovered from tuberculosis often furnishes a more difficult problem than their treatment. The occupation which was followed before the onset of the disease has frequently been unhealthful, and to return to it means to court a relapse, while the pecuniary loss in learning a new trade may be more than the patient can stand. A large number of representatives of hospitals for consumption, sanatoriums and health societies attended a conference arranged by the Charity Organization Society to discuss the after-care and employment of consumptives discharged from sanatoriums. Dr. Jane Walker, a sanatorium superintendent, said that the best trade for a discharged tuberculous patient was, with few exceptions, his old one, for thereby most money could be made, and anxiety, that potent factor in consumption, was minimized. Indeed, an unsuitable occupation with plenty of money coming in was better than an ideal one with very little coming in. However well a patient might be on leaving a sanatorium, he wanted careful watching for two years after leaving. If he had no work and his food was insufficient, he was almost certain to lose ground. No patient should be discharged from a sanatorium unless he had a friend in the neighborhood to which he was going. Dr. Burton Fannin, another sanatorium superintendent, gave an interesting analysis of the after-history of 306 patients with mild cases. Sixty per cent. went back to their former work; 31 per cent. to new work, and only 8 per cent. could find no work. Of those who went to outdoor work 76 per cent. kept well, 12 per cent. fairly well, and 10 per cent. became worse. Of those who had taken indoor work, 73 per cent. were in good health, 11 per cent. were fairly well, and 15 per cent. became worse. There was, therefore, but little difference between outdoor and indoor employments.

The Care of the Epileptic and Feeble-Minded

At a conference of poor law authorities on the subject, Dr. Jordan, medical officer of the Monyhull Colony for Epileptics and Feeble-Minded, gave an account of the work which had been done and the results achieved at the colony since it was opened in March, 1908. As a result of the training and treatment, the inmates had not only in many cases fewer fits, the feeble-minded were not only merely less feeble-minded, but they were nearly all better men and women than when admitted. The agencies of improvement were (1) work, (2) recreations and amusements, (3) education, mental and physical, (4) medical treatment. Dr. Jordan recommended that all feeble-minded persons should be removed from the workhouses and poorer private homes to institutions in which they could be properly trained. Perhaps the policy would be adopted in the future of confining all sane epileptics and feeble-minded persons in industrial colonies where the sexes could be separate after childhood.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Nov. 3, 1910

Personals

Professor Wenckebach, of Groningen, has declined a call to Marburg as director of the medical clinic.

Professor v. Leube celebrated his twenty-fifth anniversary as regular professor on the Wurzburg faculty October 31; on this occasion he was given the title of Excellency.

Centennial of the Leipsic University Gynecologic Clinic

The university gynecologic clinic of Leipsic celebrated its centennial October 30. The director of the institute, Professor Zweifel, was appointed privy counselor on this occasion. In addition, the city of Leipsic endowed two beds in the institution for needy lying-in women.

Bacteriologic Laboratories in Bavaria

Laboratories for bacteriologic investigation have been established in Munich, Erlangen and Wurzburg in connection with the universities. These institutions are to undertake investigations and make reports on bacteriologic questions for public officials and institutions and licensed physicians. The fee for examination is 50 cents (2 marks) for microscopic search for disease germs (tubercle bacilli, etc.); $1 (4 marks) for microscopic and cultural investigation of blood, etc., for disease germs; $2 (8 marks) for the more difficult cultural investigations of excreta (e. g., in typhoid); and $1.50 (6 marks) for the serum test for syphilis. If animal experiments are necessary, the fees are higher, as also for extensive reports.

Infectious Diseases in Prussia in 1908

According to the official report recently published, the deaths from influenza for 1908 were nearly twice as high as the previous year, being 2.29 per 10,000 living against 1.45 for 1907. Influenza was most prevalent in the three first months of the year. Of 8,824 deaths, 5,532 were over 60. In sixteen districts the disease was epidemic. The epidemic character was marked in boarding schools and college dormitories. The prevalence and mortality of cholera morbus was also greater than in the previous year. The mortality amounted to 26,454, or 6.8 per 10,000 living. In the first year of life it amounted to 218.65 per 10,000 living. These children were nearly all artificially fed. The mortality was much smaller in the country than in the cities.

The morbidity and mortality from typhoid for 1908 was smaller than in the previous year in accordance with the steady decrease of the last decade; it amounted to only 0.54 per 10,000 living. By bacteriologic examination, numerous bacilli-carriers were discovered. In the spread of typhoid, the transmission from person to person played the greatest rôle. There were only 390 cases of small-pox in the entire year, with sixty-one deaths, and all the cases could be referred to infection introduced from Russia.

In the general hospitals of Prussia, 22,418 persons (13,486 men and 8,932 women) were treated for gonorrhea; 23,909 persons (14,703 men and 9,206 women) for syphilis and chancroid—a total of 12.01 cases of venereal disease for 10,000 inhabitants. From puerperal fever 3,899 mothers died, 1,757 in cities, 2,142 in country districts. For 10,000 living of the female sex, two died of puerperal fever, or 30.2 for every 10,000 deliveries.

The mortality from diphtheria and croup was 9,797, 2.55 per 10,000 living; this figure is a little higher than in the previous year, but relatively lower than in all other previous years (1898: 5.56 per 10,000). There were 74,000 cases of the disease reported. From scarlet fever 8,182 persons died, 2.2 per 10,000; 81,000 cases were reported; from measles and rotheln, 7,359 died, 1.92 per 10,000, and from whooping-cough 10,672, 2.77 per 10,000.

Robert Koch on the Epidemiology of Tuberculosis

The last article by Robert Koch has just appeared in the *Zeitschrift fur Hygiene.* It is an address on the epidemiology of tuberculosis which he delivered in the Academy of Sciences. He discussed in particular the question to what the reduction in mortality from pulmonary tuberculosis in the various countries is to be attributed. As the reduction in mortality is not uniform, different causes must be responsible in different places; a reduction of virulence is not to be assumed. The decrease of consumption since the discovery of the tubercle bacillus is explained by many by the fact that in consequence of the recognition of the infectious character of tuberculosis, men are more careful to avoid the possibility of infection. While this explanation has much to its credit, it must not be regarded as a complete one. The claim put forth by German authors that social legislation, particularly insurance against illness, has caused a decrease of tuberculosis, is valid also to a certain degree. But the reduction of the mortality rate has been observed also in most other countries where laws of this sort have not yet been introduced.

In his opinion, sanatorium treatment and hospitalization of tuberculous individuals are the main factors in the reduction. Where institutional care has been most readily available, the morbidity and mortality from tuberculosis have been reduced to the greatest extent, and *vice versa.* To this Koch, like Newsholme, ascribes the facts that in England and Scotland the mortality has decreased, while in Ireland it has risen; that in Norway the mortality has increased and that it is remarkably high in Paris.

Of scarcely less importance is another factor, namely, the housing conditions. The smaller the dwelling the more infection is favored, and in this respect especially an insufficient provision for bed room is dangerous. The fact that cities with us have frequently a smaller tuberculosis mortality than the neighboring country is to be referred first to the lack of hospitals, but, secondly, to the custom of the country population to choose the poorest and smallest room in the house as the sleeping room. According to Kayserling, of the consumptives who died in their own home, 40.6 per cent. occupied one-room dwellings, 41.7 per cent. two-room dwellings. In Berlin in the course of three years more than 8,000 persons were exposed to infection by the consumptives who died in one-room dwellings.

Epidemiologic studies of this sort can be carried out only on the basis of extensive mortality statistics, which must include exact details. When the mortality curve for a larger or smaller district is rising or does not show a decline, investigation should be made to learn whether the measures adopted are effective or should be improved or supplemented. In Norway, for instance, the course of the curve for pulmonary tuberculosis instigated the building of more sanatoriums and hospitals and in this way a reduction of the curve was brought about.

Localization of Brain Functions

At the Konigsberg Naturforscher assembly, v. Monakow, the neurologist of Zurich, delivered a very interesting address on our present knowledge of the localization of brain functions. Monakow especially opposes the common view, both of clinicians and physiologists, according to which the higher psychic functions and psychologic conceptions which arise from self contemplation are referred to circumscribed parts of the cortex without any analysis into their physiologic constituents. He makes the claim that before the question of localization is raised, it must be determined what can be localized and what can not. It is not correct to conclude from the symptoms which arise after a local lesion of the brain that all the functions which appear to be disturbed are localized in this part of the brain and only in this. The localization of the symptoms must not be confused with the localization of the function. In every local lesion of the brain (whether in animal experimentation or at the sick bed) two classes of symptoms may be distinguished: 1. The residuary which depend on the lack of function of the injured part. They are more or less of an elementary nature and apply especially to the reflexes. They are constant for a definite area. 2. The temporary, these differ according to the nature of the lesion and whether the affected brain is healthy or is diseased or exhausted. They are, as a rule, temporary and usually completely disappear although after varying lengths of time. Opinions still vary as to how these disturbances, which in Monakow's opinion are not to be explained by the localization of the focus, are to be regarded and especially how their disappearance is to be regarded.

Monakow rejects the view commonly assumed at present, according to which the restoration of a function is due to its vicarious assumption by another part of the brain in place of the destroyed center (in the sense that the other parts take up the task of the destroyed part in addition to their own function). According to his view the restoration of the function destroyed at the beginning depends on the disappearance of the diaschisis. By diaschisis he means a form of shock essentially similar to other kinds of shock (psychic shock, surgical shock, apoplexy) from which it is distinguished only by the manner of its development (a division of the function into the individual constituents by the removal of a directing, combining link) and further by the fact that it is to a peculiar degree selective and in its propagation follows the line of the anatomical fibers. If from a reflex arc extending over the entire cortex and the subcortical portions of the cerebrum, and consisting of a number of members acting partly synchronously and partly successively, one of the links is destroyed by a local lesion, the other members even if they are anatomically intact may be inhibited in their function and this so much the more if the lesion affect a brain which is weakened by pathologic processes or imperfect nutrition. Under such conditions the diaschisis may only imperfectly retrogress or may become permanent, but, as is shown by animal experimentation, surgical operations, etc., it is usually a transitory phenomenon. The anatomically intact members of the reflex arc resume their activity and learn to dispense with the cooperation of the destroyed member, so that at most certain disturbances of function result, disturbances which are represented by the residuary symptoms.

To learn the function of the definite portion of brain we must study the residuary symptoms, but for a rational localization of the function, the study of the diaschisis, its appearance and retrogression is indispensable. In the localization of function, it must be particularly kept in mind how various are the individual nervous actions in character and structure and how little we are able to analyze and group nervous functions according to their physiologic factors. Even the simpler nervous activities can be localized only according to their components and not as entities. In order to be able to understand the complicated structure of functions it is necessary to consider the phylogenetic and ontogenetic development of the central nervous system with reference to the function of its individual component systems. The simplest form of the central nervous system (in the invertebrates) is represented by the ganglion system. With this is associated in the next higher stage the metameric system (lower vertebrates), then the midbrain system (bony fishes), and finally the cerebral cortex system (first in reptiles). In such a way the next higher system is always differentiated from the previous one (and this, indeed, occurs from the frontal end). Parallel with this development runs the finer structure of the organs of the body, of the muscles, the differentiation of organs of special sense, the development of the limbs, the appearance of constantly more complicated and purposive movement and the influence on action of individual experiences from combined impressions on the memory. In the coordinated movements and the sense perception of the higher animals all divisions of the central nervous system participate in common, but in a different way. In these phenomena the cortical system not only assumes the controlling rôle but cooperates with the phylogentically older systems in relatively elementary actions at least in the sense that it assumes the more specialized and later acquired components. In locomotion for instance, the metameric (spinal) system furnishes the foundation for movement in the form of the movements of the legs as they follow each other, the cerebellum provides the factors for maintaining equilibrium in rest and in movement as well as the unconscious finer regulation, the midbrain provides the connection between the individual action of the spinal segments and the cerebrum finally assumes initiation of the movement and the superintendence of it as a whole and especially the spatial direction, particularly with reference to the direction of the walk and its goal and in addition the finer adaptations of the feet to the condition of the ground.

In all accomplishments, furthermore, the chronologic factor, that is, the successive in addition to the coincident, must be taken into consideration to a great degree, the more highly developed the activities, the more the merely local factor is subordinated to the chronologic. Each function consists of synchronous and successive individual actions. In a narrowly circumscribed part of the brain only synchronous activities can be localized. The change of activity, the substitution of one activity by another, and in short the succession of functions in time evidently cannot be sharply localized. The higher the entire activity the more the chronologic factor comes to the front and in the highest, the psychic function, in the enormous predominance of the chronologic factors and in consideration of the fact that continually the same neurons are employed but constantly in other combinations and groups, it is no longer possible to determine localization.

Berlin Auxiliary Schools

The Berlin public school is to undergo a complete transformation by the establishment of the so called auxiliary schools. These auxiliary schools in future are to receive the public school children for whom systematic instruction in the ordinary schools is not successful on account of intellectual or physical defects, but who seem to be capable of instruction. The instruction in these schools is to be so arranged that the children shall either return to the ordinary school or secure in the auxiliary school such preparation for later life as is possible to them. These new schools constitute a department of the public school and are intended for children of all religious denominations. At first only one preliminary class is to be opened in each of the thirteen Berlin school districts. Further development according to the needs will be made. All such children may be received as have attended the lowest class of the ordinary schools for at least one year without success and after the close of this year remain in the lowest division of this class. This preliminary class shall be attached to an existing class of a public school for feeble minded children. After a year's attendance on the preliminary class children who have made little or no progress will be carefully examined to determine whether they shall be transferred to the auxiliary school or whether a further trial is to be recommended. No child shall remain longer than two years in the preliminary class. Idiotic children are to be sent to institutions for idiots. Children hard of hearing are to be transferred to a special department of the auxiliary school. The already existing special classes are to be united into an auxiliary school with five progressive classes. The children are to remain at least two years with the same teacher. As a rule it is provided that there shall be eighteen children to the class in the lower grade, twenty in the classes of the middle grade and twenty-two in the upper grade with twelve in the classes for those hard of hearing. In these classes the principles of coeducation of the sexes will be carried out. Children who are shown to be insane or epileptic will be excluded from the instruction in the auxiliary school and may be sent to public institutions or provided with private instruction at the cost of the municipality. Children with defective speech will be given special instruction.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Nov. 7, 1910.

Investigations on Occupational Diseases

In 1914 a congress on the diseases of occupation will be held in Vienna. As the managing committee consists of Viennese physicians an action has now been undertaken in this city as well as in the empire, to ascertain the conditions which tend to influence the health of laborers unfavorably. The investigations are directed to the following points: effect of working in hot and moist air (laundries, bakeries and mines); influence of bacterial infection (anthrax, pneumococcus) and of dust-producing occupations (skin and leather trades, the butchers' trade, the iron, stone, celluloid trades); diseases due to electricity; diseases due to industrial poisons, such as anilin dyes, mercury and lead. Special stress is laid on the study of the phenomena of fatigue, its physiology and pathology in consideration of industrial occupations, and on the effect of night work.

A Protest Meeting of the Austrian Medical Profession Against Threatened Legislation

The prolonged conflict between the medical profession engaged in dentistry and the technical dentists, who have no medical instruction, is the object of our latest legislative experiment. The government intends to create an "intermediate" profession, so to say, consisting of men who, after studying a little anatomy and pathology, may be allowed to study the pathologic conditions of the human mouth and teeth and surgery of this region. To this the medical profession could assent only on condition that the medical part of the curriculum be sufficiently thorough to make the "dentist" really capable of dealing surgically with pathologic conditions. But what the profession stoutly opposes is the plan of the government to give the same right to the present non-medical dentists, and in future to permit only the graduates of the new—as yet non-existent—dentistry school to practice dentistry. Thus, doctors of medicine would not be allowed to extract teeth or fill them, while laymen—the present dentists—would have the right to operate on fractures of the mandible, or to resect the apex of the tooth, etc. Physicians justly assert that this first legalized "raid" into the domain of the doctor will soon be followed by demands for admission to practice by opticians, masseurs, dressmakers and the like. A mass meeting of physicians took place a short time ago in Vienna, in which the presidents of various important medical societies, as well as the medical members of the Austrian Parliament, spoke before an audience of some 800 delegates of the medical practitioners of the empire. In a resolution adopted by the meeting and forwarded to the government, the representatives of the medical profession protested vehemently against the intended laicizing of medicine. If the threatened bill should become law, the profession would be prepared to order a general medical strike in the whole empire.

The New Radium Institute

A few days ago, the Radium Institute, the first of its kind on the continent, was opened in Vienna in the presence of a brilliant gathering. It is one of the few scientific institutions erected by private grants, all such buildings being usually paid for by the state. It is devoted solely to the study of the chemical and physical qualities of radium. No teaching will take place in the building. There is a large laboratory on the ground floor, for the purpose of examining spring waters for radio-activity, and also a chemical and microscopic laboratory with an ultramicroscope. An *x*-ray outfit and a plant for high-voltage currents up to 4,000 volts is installed on the first floor, while a gigantic electromagnet, weighing 1,300 hundredweight, is arranged for the purpose of investigations. The institute will not conduct medical experiments, but will, if necessary, place the substance at the disposal of hospitals. The institute has been presented with 3 grams of radium bromid, valued at $200,000, by the Academy of Sciences of Austria, to which latter corporation the institute will be annexed in the near future.

Marriages

J. Don Miller, M.D., Indianapolis, to Miss Maud Conner of Anderson, Ind., November 1.

Bernard J. O'Neill, M.D., San Diego, Cal., to Miss Anna Chapman of Sigel, Ill., November 9.

William Day Chapman, M.D., Silvis, Ill., to Miss Bessie Wayne of Orion, Ill., November 10.

John A. Salb, M.D., Indianapolis, to Miss Mary McNurney of Knightstown, Ind., November 1.

Nevin M. Wetzel, M.D., Jameson, Mo., to Miss Lillie Joachimi of Versailles, Mo., October 4.

John Francis Urie, M.D., U. S. Navy, to Miss Caroline Foulke of Richmond, Ind., November 12.

John Walter Carmack, M.D., Indianapolis, to Miss Bertha Pinber of Pleasant Lake, Ind., November 8.

Henry Irvino Berger, M.D., to Miss Ella Winkler, both of Indianapolis, at Covington, Ky., November 5.

John Kaylor Kingsbury, M.D., to Miss Florine Alcott Williams, both of Indianapolis, November 16.

Otto Carl Reiche, M.D., Laceyville, Pa., to Miss Vinnie Fenstermaker of Allentown, Pa., November 11.

John Samuel Boggess, M.D., U. S. P. H. and M.-H. Service, to Miss Ethel Keating of Columbus, Ohio, November 22.

Deaths

George Frederick Barker, M.D. Albany (N. Y.) Medical College, 1863; an eminent physicist, chemist and teacher; died at his home in Philadelphia, May 25, aged 74. He did not follow the practice of medicine, but devoted his life to chemistry. He served as professor of natural sciences at Wheaton College, Ill., professor of chemistry in the Western University of Pennsylvania, professor of physiologic chemistry and toxicology in Yale Medical School, professor of chemistry in Williams College, and from 1873 to 1900 was professor of physics at the University of Pennsylvania, and since that time emeritus professor. In 1872 he served as state chemist of Connecticut. He was given the honorary degree of Sc.D. by the University of Pennsylvania in 1898, and of LL.D. by Allegheny College in 1898, and McGill University in 1900. In 1881 he received from the French government the decoration of the Legion of Honor.

Joseph R. Gibson, M.D. Colonel, M.C., U. S. Army, retired, died at his home in Philadelphia, November 2, aged 72. Dr. Gibson entered the army as assistant surgeon in 1862, and was made captain in 1866. In 1877 he was promoted to major and surgeon, in 1894 to lieutenant-colonel and deputy surgeon general, and in 1895 was retired on account of disability in line of duty, and was advanced to the rank of colonel on account of Civil War service; in 1904 he received the brevet ranks of captain and major for faithful and meritorious services during the Civil War, and in 1866 was made brevet lieutenant-colonel for meritorious and distinguished service at Hart's Island, N. Y., where cholera prevailed.

Leonard Luton, M.D. Hahnemann Medical College, Chicago, 1867; M.C.P. and S., Ont., 1869 (Hon.); for many years a member of the Ontario Medical Council and its president in 1898; for fifteen years coroner of Elgin County and surgeon to the County Home of Industry; a member of the city council of St. Thomas for five years; and for two years chairman of the board of health and president of the board of governors of the Amasa Wood Hospital; died at his home, November 1, from uremia, aged 75.

Albert Payson Jackson, M.D. Albany (N. Y.) Medical College, 1862; a member of the Medical Society of the State of New York, and at one time president of the Genesee County Medical Society; one of the founders of the New York State Medical Association, and of the state and national associations of railway surgeons; surgeon of the western division of the West Shore Railroad; health officer of Oakfield, and coroner of Genesee County for fourteen years; died at his home in Oakfield, November 9, from heart disease, aged 67.

Robert Hunter Duncan, M.D. College of Physicians and Surgeons, Baltimore, 1885; for several years surgeon for the Pacific Mail Steamship Company; a specialist on diseases of the eye and ear, of Brooklyn; a member of the staff of the Manhattan Eye and Ear Hospital, New York City; the Eye and Ear Infirmary of Long Island College Hospital, and Williamsburg Hospital; died in the Jamaica Hospital, October 31, aged 48.

Henry Martel Newman, M.D. Georgetown University, Washington, D. C., 1876; a member of the Medical Association of the District of Columbia; and one of the staff of Providence Hospital and St. Ann's Orphan Asylum, Washington; died at his home in that city, November 11, from the effects of a gunshot wound of the head, self-inflicted, it is believed, with suicidal intent, while despondent on account of ill health, aged 54.

Frank Newell Lewis, M.D. University of Vermont, Burlington, 1882; a member of the American Medical Association, New York Academy of Medicine, and American Ophthalmological Society; surgeon to the Manhattan Eye, Ear and Throat Hospital; professor of diseases of the eye in the New York Postgraduate Medical School; died at his home in New York City, November 13, aged 53.

Montgomery Linville, M.D. Jefferson Medical College, 1873; a member of the American Medical Association, and National Association of Railway Surgeons; surgeon to the Shenango County Hospital, New Castle; formerly local surgeon to the Pennsylvania System; died at his home in New Castle, Pa., November 14, from the effects of poison, self-administered accidentally, aged 56.

William Samuel Ackert, M.D. Albany (N. Y.) Medical College, 1891; a member of the American Medical Association; attending physician to the Home for the Friendless, and Old Ladies' Home, Poughkeepsie, N. Y.; and during the summer of 1909, physician to the local tuberculosis camp; died at his home in Poughkeepsie, November 7, from valvular heart disease, aged 44.

Hubert DeLancey Knickerbocker, M.D. New York Homeopathic Medical College, New York City, 1891; a veteran of the Spanish-American War; for a time health officer of and a member of the Board of Education of Springwater, N. Y.; died at the home of his sister in Watertown, N. Y., November 8, from diabetes, aged 43.

Joseph Claybaugh Kalb, M.D. Starling Medical College, Columbus, Ohio, 1857; of McPherson, Kan.; assistant surgeon of the Forty-second Ohio Volunteer Infantry, surgeon of the Forty-fifth Ohio Volunteer Infantry, and division surgeon during the Civil War; died in Fort Worth, Texas, October 30, from cerebral hemorrhage, aged 79.

William H. Rothert, M.D. Medical College of Ohio, Cincinnati, 1889; a member of the Association of Military Surgeons of the United States; surgeon of the First Infantry, Ohio National Guard; an instructor in Miami Medical College; died at his home in Cincinnati, November 4, from cerebral hemorrhage, aged 46.

William S. Searle, M.D. University of Pennsylvania, 1859; for several years vice-president of the State Board of Medical Examiners of New York; one of the founders and for thirty-six years a member of the staff of the Brooklyn Homeopathic Hospital; died at his home in Brooklyn, October 30, aged 77.

Frank Ferrell, M.D. New Orleans School of Medicine, 1860; surgeon of the Thirty-Fourth Mississippi Infantry, C. S. A., during the Civil War; and for many years a member of the Mississippi State Medical Association; died at his home in Ashland, September 13, from emphysema, aged 78.

Jacob Harvey Edwards, M.D. University of Tennessee, Nashville, 1901; a member of the American Medical Association; of Westbrook, Texas; was thrown from his buggy and instantly killed, while making a professional call near Cuthbert, Texas, October 24, aged 37.

Lizzie Wild Charles, M.D. prominent as an organizer of branches of the Audubon Society in Illinois, and in the work of woman's clubs and schools; for two terms president of the Austin Woman's Club; died at her home in Austin, October 6, from pneumonia, aged 67.

James I. Thomas, M.D., for many years a resident of Denver; for fifty years a practitioner of the United States and formerly a member of parliament of the Dominion of Canada; died in the Denver County Hospital, March 18, from senile debility, aged 90.

Francis Bartow Gregory, M.D. Tulane University, New Orleans, 1886; a member of the American Medical Association; formerly of Lumpkin, Ga.; died recently at his home in Americus, Ga., and was buried at Lumpkin, November 4, aged 49.

William S. Chenoweth, M.D. Northwestern Medical College, St. Joseph, Mo., 1883; a member of the American Medical Association; and a veteran of the Civil War; died at his home in Fern Hill, Wash., November 1, from cerebral hemorrhage, aged 61.

William Snelson, M.D. College of Physicians and Surgeons, Keokuk, 1878; formerly of Massena, Iowa; for many years a member of the city council; died at the home of his daughter in Amarillo, Texas, October 27, from arteriosclerosis, aged 62.

Louis A. de Laureal, M.D. Homeopathic Medical College of Missouri, St. Louis, 1888; coroner of St. Martin Parish, La., for several years; and a member of the Board of Health of St. Martinsville; died at his home, August 28, aged 42.

Sumner Davis, M.D. Chicago Homeopathic Medical College, 1883; demonstrator of anatomy at his alma mater for two years; formerly of Grand Island, Neb.; died on the ranch of his son near New Plymouth, Ida., November 1.

Adolph Berger, M.D. Humboldt Medical College, St. Louis, 1862; a veteran of the Civil War; and for thirty years a member of the Board of Education of Lebanon, Ill.; died at his home in that city, November 10, aged 89.

Leslie B. Shanklin, M.D. Central College of Physicians and Surgeons, Indianapolis, 1905; of Sullivan, Ind.; a member of the American Medical Association; died in Pueblo, Colo., November 11, from tuberculosis, aged 33.

John Arthur Montgomery, M.D. College of Physicians and Surgeons, New York City, 1872; died at his home in Walton, N. Y., October 24, from injuries received in a collision between his carriage and an automobile, aged 67.

Paul Thomas Kimball, M.D. College of Physicians and Surgeons, New York City, 1887; a member of the American Medical Association; died at his home in Lakewood, N. J., November 3, from heart disease, aged 48.

Charles Borromeo Curran, M.D. Long Island College, Hospital, Brooklyn, 1893; for fifteen years a member of the staff of the Brooklyn Board of Health; died at his home, November 1, from pneumonia, aged 38.

Edward E. Brown, M.D. Albany (N. Y.) Medical College, 1879; a veteran of the Civil War; formerly of Phelps, N. Y.; died in the State Soldiers' Home, Bath, N. Y., October 6, from chronic nephritis, aged 76.

Seth G. Shanks, M.D. Albany (N. Y.) Medical College, 1875; of Albany; a member of the American Medical Association; died in the Albany Hospital, November 5, after an operation for peritonitis, aged 63.

Walter H. Fenby, M.D. University of Maryland, Baltimore, 1894; a member of the Medical and Chirurgical Faculty of Maryland; died at his home in Ruthsburg, November 5, from acute nephritis, aged 40.

George Asbury Dewey, M.D. Western Reserve University, Cleveland, 1849; surgeon in the Federal service during the Civil War; died at his home in Brooklyn, November 1, from senile debility, aged 82.

Thomas L. Blackwell, M.D. Louisville Medical College, 1874; a member of the Medical Society of the State of North Carolina; died at his home in Boonville, May 6, from disease of the liver, aged 58.

James L. Robinson, M.D. University of Louisville, 1881; a member of the Indiana State Medical Association; died at his home in Wheatland, November 8, from cerebral hemorrhage, aged 56.

George C. Young, M.D. Michigan College of Medicine and Surgery, Detroit, 1890; of Jackson, Mich.; fell through an elevator shaft, November 2, and died from his injuries November 3, aged 52.

Charles A. Dana Miles, M.D. Jefferson Medical College, 1876; for two terms coroner of Westchester County, N. Y.; died at his home in Yonkers, November 9, from acute gastritis, aged 58.

Claud M. Ferro, M.D. College of Physicians and Surgeons, Chicago, 1883; of Marshall, Minn.; died in the Minneapolis Sanitarium, recently, and was buried at Tracy, June 15, aged 59.

Ezra B. Evans, M.D. University of Virginia, Charlottesville, 1871; a member of the Indiana State Medical Association; died at his home in Greencastle, November 9, from tuberculosis, aged 64.

William J. McNeill, M.D. Detroit College of Medicine, 1899; of Detroit; died in St. Mary's Hospital, Saginaw, November

6, after an operation for the relief of intestinal obstruction, aged 39.

William M. Roberts, M.D. Northwestern University Medical School, Chicago, 1893; of St. David, Ill.; died in Graham Hospital, Canton, Ill., November 8, from heart disease, aged 45.

James Baker, M.D. Rush Medical College, 1869; physician of Fulton County, Ill.; died at his home in Table Grove, November 3, from tuberculosis, aged 65.

James A. Baird, M.D. Louisville Medical College, 1894; formerly of Moulton, Texas; died at his home in Beaumont, Texas, November 5, from nephritis, aged 54.

Andrew Drybrough, M.D. University of Edinburgh, Scotland; formerly of Evansville; died at his home in Worthington, Ind., October 20, from epilepsy, aged 41.

Harry L. Schulze, M.D. Columbus (O.) Medical College, 1883, Jefferson Medical College, 1886; died at his home in Mt Oliver, Pa, November 1, aged 53.

William G. Branch, M.D University of Louisville, 1884; a member of the Louisiana State Medical Society; died at his home in Bunkie, August 25, aged 49.

William Edward Miles, M.D. Eclectic Medical Institute, Cincinnati, 1884; died at his home in Webb City, Mo., October 30, from disease of the liver, aged 59.

Charles H. McMillan, M.D. Northwestern Medical College, St Joseph, Mo, 1893; died at his home in Leon, Kan., October 30 from tuberculosis, aged 40

Robert H. Green, M.D. St. Louis College of Physicians and Surgeons, 1886, died at his home in Poteau, Okla., November 2 from senile debility, aged 77.

Benjamin A. Bugg (years of practice, Ark.); for many years a practitioner of Blytheville; died recently at Gainesville, Texas, aged 75.

John B. King, M.D. Tulane University, New Orleans, 1875; of Segovia, Texas; was found dead in the Llano River, November 2, aged 62

Willard R Hillegas, M.D. Albany (N. Y.) Medical College, 1882, died at his home in Chicago, September 21, from angina pectoris.

Pharmacology

THE DR. BRANAMAN REMEDY COMPANY

A "Deaf Cure" Mail-Order Concern Which Has Been Declared Fraudulent

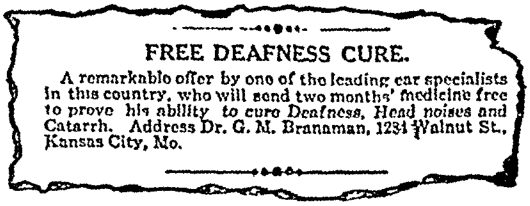
G. M. Branaman, M.D., a graduate of the Medical Department of the University of Louisville, has operated a "cure for deafness" mail-order concern in Kansas City, Mo., practically continuously since his graduation in 1891. In 1905 or 1906 he opened a branch office in Omaha, which did not stay in existence very long, apparently because it was not sufficiently profitable. Branaman's concern was known as the "Doctor Branaman Remedy Company." He employed the usual mail order medical company's method of obtaining business, that of advertising in the cheaper magazines and in (that sheet-anchor of the great American fraud) the not-too-particular religious journals Recently the United States Government through the Post Office Department, investigated the company and its methods and, as a result, has declared the business conducted by Branaman to be "a scheme and device for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises." Branaman has, therefore, been deprived of the use of the United States mails by means of a fraud order. Judge Goodwin, in his memorandum as assistant attorney general to the postmaster-general, describes in detail the methods pursued by the Branaman Remedy Company, and what follows is a synopsis taken from this report.

HOW PATIENTS WERE OBTAINED

Patients—or victims—were secured by inserting, in newspapers and magazines, advertisements similar to the one reproduced on this page (Fig. 1). The drawing part of this advertisement was the offer to "send two months' medicine free" to those who applied for it. Those who answered the advertisements were sent a booklet entitled "The New Treatment That Cures," and containing testimonials and a description of Branaman's "treatment." A letter also was sent together with that inevitable adjunct of the mail-order quack—the "symptom blank." The prospective victim was asked to fill out and return the blank and was told that on doing so his case would be carefully considered and if believed to be a curable one, he would be furnished two months' medicine free. He was also told that Dr. Branaman would accept only such cases as he believed to be curable! If the symptom blank was not returned a series of follow-up "form" letters printed to imitate personal, typewritten communications was sent, each "letter" urging that the blank be filled out.

THE "FREE TREATMENT" AS A BAIT

When the victim filled out the blank and sent it to Branaman, he received a "diagnosis" letter—also of the circular letter variety, printed to imitate typewriting. At the trial it was shown by the government that Branaman had but two forms of "diagnosis" letters—one informing the patient that he had "catarrh," the other "diagnosing" the case as one of "deafness" No matter which of the two letters the patient received, he was informed that his case was far too serious a one to be cured by medicine alone, and that, therefore, there was no use in Dr. Branaman sending the two months' free treatment promised in the advertisement and circular letters. So serious was the case, he was told, that it was imperative that he have Dr. Branaman's "Combination Treatment," which involved the use of his "electro-magnetic head-cap" (Fig. 2) in conjunction with the medicines. He was further informed that this "combination treatment" would cure his disease and that if he would pay $8 for the head-cap the 'treatment" would be sent



FREE DEAFNESS CURE.

A remarkable offer by one of the leading ear specialists in this country, who will send two months' medicine free to prove his ability *to cure Deafness, Head noises and* Catarrh. Address Dr. G. M. Branaman, 1234 Walnut St., Kansas City, Mo.

Fig 1.—Photographic reproduction of a typical Branaman advertisement.—From *Word and Works*

If the $8 was not forthcoming, follow-up letters were sent at regular intervals until either all the letters of the series had been mailed or the $8 had been extracted. These letters, like the others, were printed to simulate personal typewritten communications, the name and address of the individual to whom they were sent being "filled in" by means of a typewriter.

CURES PROMISED IN INCURABLE CASES

In preparing the case against Branaman the government inspectors corresponded with the concern as supposed patients. Five letters were sent under different names and from widely separated parts of the country. The same number of symptom blanks were filled out and each hypothetical case described by the inspectors was one of total and incurable deafness In spite of the impossibility of curing such cases, the inspector, in every instance, received the stereotyped request for $8, with the promise of a sure and permanent cure if it was paid. In each instance the regular "deafness" diagnosis letter was sent, followed by the follow-up series.

The inspector remitted $8 in one of the hypothetical cases and received "[illegible] head-cap" and the medicines. The "[illegible] arrangement of straps and metal pieces to be worn by the patient and was claimed to produce a current of electricity through the ears which, it was alleged, would revivify the nerves and other structures of the ear. With the "head-cap" came some tablets, three bottles of liquid and a vaporizer for spraying the nose and throat. The drugs were analyzed by the chemists of the Department of Agriculture, who reported them as having the following composition:

Tablets

Strychnin sulphate .	1/60 gr
Milk sugar q s	1 gr

One of these was to be taken before each meal

Ear Drops

Carbolic acid	3 12 per cent
Glycerin	25 00 per cent
Saturated solution of boric acid	71 88 per cent

The instructions with this bottle were to put three drops of the liquid in the ear each night

Vaporizer Liquid

Menthol crystals	1 18 per cent
Camphor gum	1 18 per cent
Thuja oil	0 03 per cent
Petrolatum	97 61 per cent

This was to be used as a spray for the nose and throat

Gargle

Bicarbonate of soda	2 91 per cent
Powdered borax	2.91 per cent
Carbolic acid	0 28 per cent
Glycerin	5 09 per cent
Burnt sugar, sufficient to color	
Water	88 81 per cent

The directions which went with this were ' Add 1 teaspoonful to 8 tablespoonfuls of hot water Snuff up nose Gargle throat night and morning, half each time"

Fig 2—Photographic reproductions from Branaman s booklet, "The New Treatment That Cures, showing the highly imaginative pictures of the electro magnetic headcap' in action

The evidence at the trial showed that the "head cap" cost Branaman about $1 50, the vaporizer about 30 cents and the medicines just described not over 50 cents For this the patient paid $8

A FRAUDULENT TESTIMONIAL

One of the testimonials published by Branaman in his booklet, The New Treatment That Cures," purported to be from one John Turner of Kansas City, Mo It was as follows

> 'I contracted cold during the Civil War It grew worse from year to year Finally my eyesight began to fail my eyes became watery I could not distinguish a man across the street My ears began to close and my hearing to fail I had distracting head noises I was worse in changeable weather My throat was dry, my ears felt full, I could hear sounds but could not distinguish words Finally I got so deaf I could not hear the clock or doorbell I went to Dr Branaman a very skeptic man I had no faith in doctors I began the treatment with excellent results My head became clear the noises began to subside my eyes gained and soon I was all right, my hearing perfect

This case was investigated by the post office inspector, who went to Turner's house Turner himself was not at home but his wife said that her husband had not been benefited by the Branaman treatment, that his hearing was so bad that he did not dare to go to work in the stock yards for fear of being run over and killed from his inability to hear anything. Mrs Turner further stated that all the inquiries her husband received regarding his cases were turned over to Branaman, Turner himself being unable either to read or to write

THE DEFENSE AND THE CHARGE

Branaman's defense in regard to offering to cure five plainly incurable cases of deafness was that he was out of the city when some of the five cases were accepted for 'treatment," and that his assistant, Dr Perkins, must have been responsible On cross examination however, Branaman retracted his previous statement as to his absence from the city on those dates

Judge Goodwin, in his memorandum as assistant attorney-general to the postmaster general, gave many reasons for holding the opinion that Branaman's business was a fraudulent one They may be summarized thus

Fraud No 1—Five different cases of incurable deafness from various parts of the country were accepted—and, as the evidence showed, intentionally accepted—for treatment and a promise of a sure cure made The number indicated that it was Branaman's practice to accept such cases and to make such promises

Fraud No 2—Branaman's continued publication of Turner's testimonial to the effect that his hearing was perfect and that he had been cured of deafness, when Branaman knew that Turner was so deaf as to be incapacitated for work

Fraud No 3—The inducement held out in the advertisements of a "free two months' treatment" when, in fact, the intent was to obtain $8 for goods costing Branaman $1 50

Fraud No 4—The representation that the case of each patient would be considered individually and that "treatment" adapted to the necessities of the specific cases would be used, when the evidence showed that the same "treatment" was sent to practically all persons sending the necessary $8

As a result of his findings the assistant attorney general declared "I find that the business being conducted through the post office at Kansas City, Mo, under names of Dr. Branaman Remedy Company and Dr J M Branaman, is a scheme and device for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, and I therefore recommend that a fraud order be issued prohibiting the delivery of mail and the payment of money orders to such addresses . . ."

The order was issued

Correspondence

The Correct Name of the Rocky Mountain Spotted-Fever Tick

To the Editor—In a recent issue of The Journal (October 29 p 1574) Mr Nathan Banks charges me with 'gross violation of the rules of nomenclature," in that I have used the name *Dermacentor andersoni* instead of *D venustus* for the tick that transmits Rocky Mountain spotted fever Although the point at issue is a very technical one, it is not without its practical side, and in order to avoid a further confusion, which would result were Mr Banks' interpretation accepted, the following facts bearing on the case are made public

The name *Dermacentor venustus* Marx (a manuscript name) was originally published by Neumann in 1897, as a synonym of *D reticulatus*, its type locality was given as Texas and New Mexico

According to "Opinion 4" of the International Commission on Zoologic Nomenclature, "manuscript names acquire standing in nomenclature when printed in connection with the provisions of Article 25, and the question as to their validity is not influenced by the fact whether such names are accepted or rejected by the author responsible for their publication"

The name *D venustus* received status in 1897 and was not available as a new specific name eleven years later (1908), when Mr Banks published it as such. Its status in 1897 as given to it by Neumann is this: It is a synonym of *D. reticulatus* as interpreted by Neumann, namely, *D. reticulatus* of Europe plus specimens examined by Marx from Texas and New Mexico, plus certain other forms.

Two possibilities are present: (1) If really identical with *D. reticulatus*, the name *D. venustus* drops into synonymy and cannot be used for the spotted-fever tick. (2) The only way of separating the name from *D. reticulatus* is by finding the original specimens from Texas or New Mexico and showing that they are not identical with *D. reticulatus.*

In material recently at my disposal, I had specimens of the Marx collection labeled *Dermacentor venustus* from both Texas and New Mexico. These are the specimens on which Neumann published in 1897, and it is the Texas specimen from sheep which I designated as the type. These specimens are clearly distinct from the European *D. reticulatus*, and they represent the form which I have published as *D. venustus.*

Mr. Banks was present at a meeting of the Entomological Society, Jan. 10, 1907, when I showed drawings of the European *D. reticulatus*, and explained the differences between this and the various American forms. He also visited my laboratory for the specific purpose of examining Marx' material, and at that time the originals of *D. venustus, D. occidentalis* and *D. andersoni* were placed before him, together with drawings of the stigmal plates. He later (1908) published "*Dermacentor venustus* n. sp.," admitting that it was Marx' manuscript name and giving among the localities of specimens both New Mexico and Texas; these were the original localities of Marx' specimens which Dr. Banks had examined in the visit referred to and as published by Neumann.

Mr. Banks states in his recent letter that I have applied the name *D. venustus* to a form he did not study. This statement is difficult to harmonize with the fact that he examined the specimen on which I published and he quotes (Bull. 15, Bureau of Entomology, U. S. Dept. Agric., 1908, p. 47) the very specimen which I took as a type, namely, from "Texas (on sheep)."

If the name *venustus* dates from 1908 (as Mr. Banks claims) instead of from 1897 (as I maintain), it is now clear that Mr. Banks' description must include three sets of type specimens, namely, Marx' original material of *D. venustus*, my original type of *D. andersoni*, and the material which Mr. Banks has informed me he has selected as type, but which he also said was not from Marx' collection.

In adopting *venustus* for Marx' Texas form I have taken the only way I see open to preserve the name in question (a name proposed by a deceased colleague), namely, by attaching it to the material published in 1897. This eliminated the name *venustus* from the spotted-fever tick, for which the manuscript name *D. andersoni* had already been published and which was therefore retained.

Were the premise correct, that Marx' specimens from Texas and New Mexico are identical with the specimens from Montana, then *D. venustus* would of necessity be the correct name for the Rocky Mountain spotted-fever tick, but this premise is erroneous, and the name *venustus* must be applied to the species containing the original specimen designated under this name.

Charles Wardell Stiles, U. S. Public Health
and Marine-Hospital Service, Washington, D. C.

Offer to Medical Libraries

To the Editor:—The year 1898 will be known in the annals of medicine by an epoch-making event. In that year *Libraries*, a bi-monthly publication devoted to the interests of medical libraries, first saw the light of day in the city of Denver. For several years it made its irregular and spasmodic appearance and closed its career in a blaze of glory A.D. 1902. Its circulation reached the astounding number of 120. What it lacked in numbers it made up in quality. Among its admirers, subscribers and contributors it counted the foremost librarians of the day—Dana, Fletcher, Chenley, Billings, Grace Bryant, Fisher, Parsons, Dudley, Beer, Aheren, Putnam, Bowker, Meyers, Utley, Bowen, Noyes, Crunden, Chase, Dewey, *Merrill*, and the medical luminaries—Osler, Chadwick, Keen, Da Costa, Musser, Simmons, Edward Jackson, Hare, Horatio Wood, Solis-Cohen, Hutchinson, Gould, Dock, Senn, Bonney, Solly, Shattuck, Bayard Holmes, Jacobi, Wilson, Sewall, Eskridge and many other makers and lovers of books.

Now comes the proud editor and publisher of said defunct periodical and offers to send to all medical librarians and to all who are interested in freak medical journalism complete sets of Volumes 2, 3 and 4 and incomplete sets of Volumes 1 and 5 for the asking, as long as the supply lasts. All the said sad editor asks in return is that these, his dear departed ones, be reverently laid out, decently shrouded, adequately coffined, properly epitaphed, securely inhumed and unostentatiously gathered unto their fathers in God's acre. He devoutly and prayerfully hopes for their resurrection.

C. D. Spivak, M.D., 1421 Court Place, Denver.

Removal of Moles, Warts and Other Benign Growths

To the Editor:—Dr. J. C. Bloodgood, in his article on "Surgical Treatment of Cutaneous Malignant Growths" (The Journal, Nov. 5, 1910, p. 1615), asserts that he was "the first, or at least one of the first, to call attention to the importance of removal of certain forms of benign growths, pigmented moles, some seven years ago." I wish to call attention to the fact that Dr. S. H. Weeks, of Portland, Maine, professor in surgery in Bowdoin College, taught the importance of removal of moles, warts, etc., as soon as seen by the surgeon, as long ago as 1895 and 1896; thus he had priority of Dr. Bloodgood by seven or eight years.

O. I. Bemis, Bangor, Maine.

Prevention of Perforation in Submucous Resection of the Nasal Septum

To the Editor:—Permit me to offer a suggestion in connection with Dr. Nelson's method of preventing a perforation in submucous resection (The Journal, Nov. 19, 1910, p. 1875): Incise the mucous membrane and perichondrium at B instead of at A and retract. Then dissect forward the tissue anterior to the incision and incise the cartilage at A. This allows the flap from B to A to cover the stump of cartilage. If this is not done the incised membrane undergoes cicatricial retraction and leaves a dry and crusted surface, besides delaying healing.

Albert Bardes, New York.

The Public Service

Medical Department, U. S. Army

Changes for the week ended Nov. 19, 1910.

Davis, W. Cole, lieutenant, November 11, left Fort Ethan Allen, Vt., on ten days' leave of absence.

La Garde, Louis A., colonel, November 13, left army medical school, Washington, D. C., on ten days' leave of absence.

Lowe, Thomas S., M.R.C., Nov. 8, left Presidio of Monterey, Cal., for temporary duty at Whipple Barracks, Ariz.

Long, Charles J., D.S., November 11, leave of absence extended twenty days.

Stone, John H., major, November 12, relieved from duty at Fort Sam Houston, Texas, and ordered to Fort McIntosh, Texas, for duty.

Grubbs, Robert B., major, November 12, relieved from duty at Fort McIntosh, Texas, and ordered to Fort Bliss, Texas, for duty.

Dutcher, B. H., major, Nov. 14, 1910, leave of absence further extended twenty-eight days.

Mason, George L., D.S., November 14, left from temporary duty at Fort Lincoln, N. Dak., and en route to Fort Yellowstone, Wyo.

Woodall, William P., captain, November 14, left Fort D. A. Russell, Wyo., on fifteen days' leave of absence.

Patterson, Robert F., D.S., November 15, relieved from duty at Fort Sheridan, Ill., and ordered to the Philippine Islands for duty on transport sailing from San Francisco about Feb. 15, 1910.

Bernheim, Julian R., D.S., November 15, relieved from duty in the Philippine Islands and ordered to proceed to San Francisco on the transport sailing from Manila, P. I., about March 15, 1910. On expiration of his leave of absence will proceed to Fort Sheridan, Ill., for duty at that station.

Tasker, Arthur N., lieutenant, November 15, granted leave of absence for one month and fifteen days.

Walker, Thomas C., M.R.C., November 16, leave of absence extended twenty days.

Phillips Hiram A., lieutenant, November 16, ordered to proceed to Fort Andrews, Mass., for duty at that station.

Ingalls, R. E., D.S., November 9, granted ten days' leave of absence.

Medical Corps, U. S. Navy

Changes during the week ended Nov. 19, 1910.

Shook, F. M., P. A. surgeon, detached from the naval medical school, Washington, D. C., and ordered to duty at the naval hospital, New York.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended Nov. 16, 1910.

Gassaway, J. M., surgeon, leave granted Oct. 14, 1910, amended to twenty-four days from Oct. 7, 1910.

White, J. H., surgeon, granted ten days' leave of absence from Nov. 11, 1910.

Nydegger, J. A., surgeon, granted one month's leave of absence from Nov. 10, 1910, on account of sickness.

Sprague, E. K., surgeon, leave of absence granted Oct. 14, 1910, amended to read four days from Oct. 28, 1910.

Grubbs, S. B., P. A. surgeon, granted twenty-one days' leave of absence from Nov. 7, 1910, on account of sickness.

Foster, M. H., P. A. surgeon, granted seven days' leave of absence from Oct. 3, 1910, under paragraph 191, Service Regulations.

Korn, W. A., P. A. surgeon, directed to proceed to Pittsburg, on special temporary duty, Nov. 7, 1910.

Earle, B. H., P. A. surgeon, granted three days' leave of absence en route to station.

Roberts, Norman, P. A. surgeon, granted two days' leave of absence from Nov. 7, 1910, under paragraph 191, Service Regulations.

Smith, F. C., P. A. surgeon, granted seven days' leave of absence from Nov. 3, 1910, under paragraph 191, Service Regulations.

Spratt, R. D., P. A. surgeon, granted seven days' leave of absence from Oct. 14, 1910, under paragraph 191, Service Regulations.

Coffee, Joseph H., acting asst. surgeon, granted ten days' leave of absence from Nov. 5, 1910.

Schuster, B. L., acting asst. surgeon, granted twenty-two days' leave of absence from Nov. 7, 1910.

Stuart, A. F., acting asst. surgeon, leave of absence granted for thirty days from Oct. 1, 1910, amended to read thirty days from Oct. 4.

Walker, T. D., acting asst. surgeon, granted eleven days' leave of absence with pay and one day's leave without pay from Nov. 7, 1910.

White, R. C., acting asst. surgeon, granted thirty days' leave of absence from Nov. 7, 1910.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SODIUM CITRATE IN FURUNCULOSIS

To the Editor:—Will you kindly refer me to literature on the subject of Wright's treatment of suppurating lesions (as furuncles) by the use of solutions of sodium citrate and sodium chlorid?

J. L. L.

Answer.—We are unable to find any reference in recent literature to the use of sodium citrate in furunculosis. Sir A. E. Wright recommends vaccine treatment with staphylococcus vaccine guided by the determination of the opsonic index. He has recommended citrate of sodium for the purpose of preventing thrombosis in typhoid fever. Perhaps it is this use of sodium citrate that our correspondent has in mind.

HYPNOTISM AND SUGGESTIVE THERAPEUTICS

To the Editor:—Please answer the following questions:

1. Do you consider the subject of hypnotism of much value in the psychoneuroses?

2. Would it be worth while for a general practitioner to acquaint himself with the subject of hypnosis?

3. Can you refer me to literature on hypnotism and suggestive therapeutics?

W. B. N., Anderson, S. C.

Answer.—1. In competent hands, hypnotism must be regarded as a valuable therapeutic procedure for a large number of the psychoneuroses, especially those of a severe or complicated type. In many cases, however, the same results can be obtained by the methods of waking suggestion and by persuasion.

2. Before resorting to hypnotism the general practitioner should thoroughly acquaint himself with the methods of suggestion and persuasion which do not involve hypnosis. For such purpose the methods of persuasion advocated by DuBois are valuable, and a thorough study of his book is recommended. Suggestion in the hypnoidal state as recommended by B. Sidis (*Journal Abnormal Psychology,* July, 1909; also *Monthly Cyclopedia and Medical Bulletin,* August, 1909) can be employed, and in general is to be preferred to hypnotism for a practitioner who is not an expert in the latter art. If hypnotism is undertaken, Barker's suggestion that a third person should be present is worth remembering.

CHANCRE AND CHANCROID

To the Editor.—Please differentiate briefly between chancre and chancroid, describing the appearance and progress of each, within a month from infection on the labia of the female. In such a case, under which head would you class a painful, swollen, suppurating sore which is spreading rapidly? Do chancre and chancroid both come under the head of syphilis? If not, please indicate the treatment for the latter.

W. O. L.

Answer.—A chancre is the initial lesion of syphilis, and is due to the action of *Treponema pallidum*. It appears about twenty days after infection and is generally single. It usually consists of a small papule, which may ulcerate, but which produces little pus and does not tend to spread beyond its point of origin. Its secretions do not produce similar lesions in other parts of the skin of the same patient, *i. e.*, it is not auto-inoculable. The base and surroundings of the ulcer are usually of a marked hardness, but it is not painful. It leads to a general enlargement of all of the lymphatic glands, which shows no tendency to suppuration but is very persistent. Usually in the course of a month or six weeks the chancre heals, leaving ordinarily a slight scar, but it may persist longer. Spirochetes (treponemata) can be demonstrated in the secretions from a chancre and the Wassermann reaction is positive in the latter part of its course.

A chancroid is a local lesion, believed to be due to a streptobacillus discovered by Ducrey, which ulcerates rapidly, is painful, spreads extensively, produces much pus and is auto-inoculable. It appears in two or three days after infection and is frequently multiple. Only the lymphatic glands adjacent to the area of infection become enlarged, but they soon break down, forming a bubo. The base of the chancroid is not indurated. The chancroid leads to no specific constitutional affection but may produce septicemia. It does not contain treponemata and does not give the Wassermann reaction. While chancroid has no relation to syphilis, it may accompany and conceal the initial syphilitic lesion. In spite of its local character, a chancroid may pursue a chronic course and undermine the general health, producing a severe cachexia.

The ulcer described is probably a chancroid. The part should be carefully cleansed and the surrounding skin or mucous membrane should be protected as carefully as possible against auto-inoculation. A local anesthetic, like cocain, should be applied before cauterizing. The best caustic is probably the application of the thermal or galvanocautery, but if this is not available, chemical caustics may be used. The best is fuming nitric acid. A preliminary application of pure phenol (carbolic acid) may be made, by which the sensitiveness of the ulcerated surface is diminished. The phenol should be carefully removed by wiping with absorbent cotton. Then an application of pure nitric acid should be made to the surface of the ulcer. The careful removal of the phenol is essential, as there may be danger of nitric acid and phenol forming an explosive compound. When the slough has separated the resulting ulcer should be treated like any other ulcer by strictly aseptic methods. The general health should be cared for by appropriate hygienic measures and supporting medicinal agents.

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

MEDICAL EXPERT TESTIMONY

The problem of medical expert testimony is one which confronts both the medical and the legal professions. Neither physicians nor lawyers alone can solve it. The only hope for its equitable adjustment lies in cooperation between the two professions. As was remarked editorially last week, this fact has been realized in Missouri by both the medical profession and the bar, and the result has been the appointment of a joint committee on medical expert testimony from the Missouri State Medical Association and the Missouri Bar Association. This committee, recognizing that the present situation in most states is absurd and grotesque, has drafted a bill amending the Missouri statutes in the hope of improving the procedure in legal battles in which medical expert testimony is necessary.

Previous efforts in this direction in other states are interesting. In only two states, Michigan and Rhode Island, have laws on this subject been enacted. The Michigan statute endeavors to regulate the abuse of medical expert testimony by removing the incentive of large fees, and provides that no expert witness shall receive as compensation in any given case a sum in excess of the ordinary witness fees, unless the court awards a larger sum. It also provides that not more than three experts shall be allowed to testify on either side as to the same issue, and that in trials for murder, in which expert opinions are required, the court shall appoint one or more suitable persons, not exceeding three, to investigate the issues involved and to testify at the trial, compensation for these experts to be fixed by the court and paid by the county. This provision takes the summoning of expert witnesses out of the hands of lawyers for the defense and also limits the amount of money which can be spent for such purposes.

The Rhode Island statute provides that any justice of the superior court may, in either a civil or criminal case, on the motion of either side, appoint one or more persons as expert witnesses. The amount of compensation for such witnesses is fixed by the court but paid by the party asking for their appointment. Such witnesses report their findings in writing to the court and their report forms part of the record of the case and may be produced in evidence at the trial. The expert witnesses are required to attend the trial and they may be cross-examined by either side. In personal injury suits, the court is authorized to require a physical examination of the plaintiff.

At the last session of the legislatures in Maine and New York, bills to regulate expert evidence were introduced but failed to pass. The Maine bill provided that the judge in any superior court might, on his own initiative, appoint one or more experts to investigate the questions at issue, who should prepare themselves to testify in relation thereto, if called on. Such experts, after having been appointed, might be called as witnesses by either side or by the court and when so called would be subject to full examination and cross-examination. Their compensation was to be fixed by the court. The New York bill provided that the justice of the supreme court should designate at least ten and not more than sixty physicians in each judicial district who might be called as medical expert witnesses by the court or by either party to a civil or criminal action in any of the courts of the state, and that such physicians when so called should testify and be subject to examination and cross-examination, and their compensation be fixed by the trial judge and paid by the county in which the trial was held. An additional section specifically provided that either of the parties in the case should have the right to call other expert witnesses, as at present.

The proposed bill in Missouri provides that any judge of any court of record in hearing any case, either civil or criminal, shall "on his own motion or that of any party therein, at any time or during the trial thereof when the ends of justice seem to require it," appoint one or more expert witnesses whose fees should be fixed by the judge and paid by the party moving for their appointment. In criminal cases, on request of the defendant, expert witnesses may be furnished at the expense of the state at the discretion of the court. Such witnesses shall be sworn to make a faithful and impartial examination of the matter submitted to them for investigation and shall report their findings in writing, such report to be filed, not as evidence, but as a basis for the examination of the expert witnesses by the court or by the counsel for either party. It will be noted that the proposed law in Missouri differs from the Rhode Island statute in that, in Rhode Island, the report of the expert witnesses is made a part of the evidence in the case. The Missouri bill further provides that either party to the cause shall have the right of examination and cross-examination. In civil suits for damages following personal injury, the judge may require the plaintiff to submit to a reasonable examination by an expert appointed by the court. The court may also require the defendant to permit of the examination of the place and cause of the injury by experts appointed by the court. Compensation is limited to ordinary witness fees, except by order of the court, and the receipt or payment of any larger sum is made a misdemeanor punishable by a fine not exceeding $1,000, or imprisonment not exceeding one year, or both.

It is evident, from the two laws enacted and those proposed, that the regulation of compensation for expert testimony is regarded as one of the most important means of correcting existing abuse. The appointment of expert witnesses by the court is unquestionably a step in the right direction. Whether the report of such witnesses should be regarded as evidence or merely as a basis for examination is for those familiar with the rules of evidence to determine. The limiting of expert witnesses to those selected by the court, and the provision for a written report on the questions at issue, should go far toward eliminating the self-constituted "expert" who, oftentimes without adequate professional knowledge or standing, and animated mainly by a desire for large fees, can be secured in almost any case to testify to nearly anything which partisan advocates may desire.

In this connection, the resolutions adopted by the Committee on Medical Expert Testimony of the American Medico-Psychological Association, which recently appeared in the *American Journal of Insanity*, are of interest. The committee's declarations relate mainly to medical expert testimony in cases in which insanity is pleaded as a defense. They are:

1. The proved rarity of wrong acquittals on the ground of insanity is the strongest evidence that the abuse of the insanity plea in criminal cases has been unwarrantably exaggerated.

2. The insanity plea is not raised as often as it should be to prevent the frequent miscarriage of justice arising from the conviction and imprisonment of insane persons whose true mental condition has not been recognized.

3. The abuses which have crept into the method of presenting medical expert testimony have been largely the result of established legal tests and proceedings, although their correction does not require radical change in the laws.

4. Inaccessibility of the evidence on both sides of the case is the chief cause of defective medical testimony.

5. Whenever possible the medical witness should not testify unless he has had an opportunity to make both a mental and physical examination of the person in whose behalf the plea of insanity is raised.

6. We consider the hypothetical question as ordinarily presented to be unscientific, misleading and dangerous to medical repute, and that the evidence on both sides should always be included in its presentation to the medical witnesses.

7. In all criminal cases, absolutely equal rights should be accorded the medical witnesses for both the prosecution and the defense for the examination of the person alleged to be insane.

8. In our judgment the judiciary should by legal enactment be allowed more latitude in enlightening the jury and enabling it to comprehend the nature and meaning of the medical testimony laid before it.

9. We recommend as advisable the adoption, wherever possible, of the so-called Leeds method of preliminary consultation by medical witnesses on both sides of the case as to its status.

10. We advocate a freer use of appointments of commissions by the court.

11. A period of hospital observation of all persons committing crimes in whose defense the plea of insanity has been raised is by far the best method yet devised for securing impartial and accurate opinions, silencing popular clamor, avoiding prolonged and sensational trials and saving expense to the state; we also advocate the enactment in every state of laws similar to those of Maine, New Hampshire, Vermont and Massachusetts, providing that such persons may be committed by the court to a state hospital for the insane, there to remain for such time as the court may direct, pending the determination of their insanity.

12. It is the sense of the association that it is subversive of the dignity of the medical profession for any of its members to occupy the position of medical advisory counsel in open court, and at the same time to act as expert witness in a medicolegal case.

13. We regard the acceptance by a physician of a fee that is contingent on the result of a medicolegal case as not in accordance with medical ethics and derogatory to the good repute of the profession, and advocate the regulation of the practice by legislation.

14. We are in favor of any legislation that will secure a definite standard of qualification for medical men giving expert testimony.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Fourth Month—Third Weekly Meeting

TUBERCULOUS DISEASE OF THE SPINE

Pathology

Pathology of the tubercle. Changes in body of the vertebræ; of the processes. Secondary changes in bony structures, kyphosis, resulting deformities. Process of repair. Abscess formation. Changes in spinal cord, membranes and nerves.

Symptoms

Attitude: Movements of body, attitude when different regions are affected, rigidity of spine.

Pain: Cause, location, diagnostic value. Eye symptoms, cough, dyspnea.

Deformity: Angularity.

Abscess: Location, pointing, prognosis.

Paralysis: Location, partial or complete, reflexes, sphincters.

Treatment

General Treatment: Fresh air, sunshine, diet, medicinal treatment.

Local Treatment: 1. Bed treatment, indications, appliances. 2. Ambulatory treatment by jackets and braces; indications, detail methods of application, appliances used for deformities in different regions.

Treatment of abscesses: Expectancy, aspiration, incision.

Treatment of paralysis.

Treatment of diseased vertebræ.

State Boards of Registration

COMING EXAMINATIONS

California: Los Angeles, December 6-9. Sec., Dr. Charles L. Tisdale, 929 Butler Bldg., San Francisco.

Delaware: Regular, Dover, December 13-15; Homeopathic, Wilmington, December 13-15. Secretary of the Medical Council, Dr. H. W. Briggs, Wilmington.

Kentucky: Louisville, December 15-17. Sec., Dr. J. N. McCormack, Bowling Green.

Maryland: 1211 Cathedral St., Baltimore, December 13-16. Sec., Dr. J. McPherson Scott, Hagerstown.

Ohio: Cincinnati, December 6-8. Sec., Dr. George H. Matson, State House, Columbus.

Pennsylvania: Regular and Homeopathic, Philadelphia, December 6-9; Eclectic, Harrisburg, December 6-9. Secretary of the Medical Council, Dr. Nathan C. Schaeffer, Harrisburg.

Virginia: Lynchburg, Dec. 20-23. Sec., Dr. R. S. Martin, Stuart.

New Jersey June Report

Dr. H. G. Norton, secretary of the New Jersey State Board of Medical Examiners, reports the written examination held at Trenton, June 21-23, 1910. The number of subjects examined in was 9; total number of questions asked, 135; percentage required to pass, 75. The total number of candidates examined was 41, of whom 34 passed and 7 failed. The following colleges were represented:

PASSED

College.	Year Grad.	Per Cent.
Johns Hopkins University	(1910)	83.7, 88.6

The following questions were asked:

[Answer any ten questions on each paper, but no more.]

ANATOMY

1. Describe the coccyx. Name the muscles attached to it. 2. Describe the ileocecal valve. What is its function? 3. Give the coverings of a femoral hernia from within outward. 4. Give the minute structure of the kidney. 5. Describe the inferior radio-ulnar articulation. 6. Describe the suprarenal glands. State their function. What would be the effect of their removal? 7. Describe the glands and villi of the intestines. 8. Give the foramen of exit, the distribution and the function of the oculomotor nerve. 9. Where does the glossopharyngeal nerve rise and what structures are supplied by this nerve and its branches? 10. Locate and describe the lymphatics of the front of the thorax. 11. Give the origin, course and branches of the temporal artery. 12. Name the principal centers of organic function in the medulla oblongata. 13. Locate the respiratory center. 14. From what portions of the cortex cerebri do the arm, face and leg receive their motor impulses? 15. What would be the effect of a transverse section of (*a*) the anterior root, (*b*) the posterior root of a spinal nerve?

HISTOLOGY—PATHOLOGY—BACTERIOLOGY

1. Describe the rôle of uric acid in gout. 2. Give etiology of valvular heart disease. 3. How does aortic insufficiency affect the circulation of the blood? 4. Define anemia. 5. Define immunity. 6. Describe a microscope and such accessories as you would use in histologic work. 7. Describe preparation of objects for microscopic examination. 8. Describe the cell body. 9. Describe the process of mitotic cell division. 10. Define chromatolysis. 11. What are bacterins? 12. What is the effect of an injection of bacterial vaccine? 13. Describe preparation of and varieties of culture media. 14. Give technic of making plate cultures. 15. Give method of examining sputum for detection of tubercle bacilli.

CHEMISTRY

1. Discuss arsenic and mention its properties, uses and compounds. Give antidote for poisoning by arsenic. 2. Name three elements in the potassium group with their symbols and atomic weights. 3. Give the symbol and quantivalence of sulphur. What are the principal oxygen compounds of sulphur? In what form is it

used as a germicidal and disinfecting agent? 4. (*a*) State the normal reaction of urine (*b*) To what is it due? (*c*) State the variations in normal specific gravity (*d*) What pathologic conditions are indicated by a very high or a very low specific gravity? 5 Give the chemical formula and derivation of acetic acid Mention the most important acetates 6 Give the names and formulas of three gases used for producing general anesthesia. 7. What are enzymes? Mention those of animal origin and where found 8 Give test for the detection of bile in the urine 9. Which are the principal opium alkaloids and with what acid are they combined in opium? 10 What is cholesterin? In what pathologic condition is it found? 11 Give the chemical formulas and common names of magnesium hydrate and magnesium sulphate 12 (*a*) What is tartar emetic? (*b*) What are the symptoms of poisoning by tartar emetic? 13 (*a*) What is hemoglobin? (*b*) In what pathologic condition is hemoglobin found in the urine? 14 (*a*) What is the ammonium radical? (*b*) Give chemical formula of the ammonium compound contained in aromatic spirit of ammonia 15 (*a*) Give the source and chemical formula of common salt (*b*) How are chlorids chemically recognized in urinalysis?

HYGIENE AND MEDICAL JURISPRUDENCE

1 Describe the methods usually employed for the sterilization of drinking water 2 (*a*) What conditions of soil tend to promote health? (*b*) What conditions tend to impair health? 3 State (*a*) the main source of infection in tuberculosis; (*b*) what personal hygienic measures may be employed to prevent its spread? (*c*) what disinfectants and what method of application will tend to prevent house infection? 4 Outline in detail the precautions that should be taken in the treatment in scarlet fever to prevent the spread of the disease 5 What diseases spread by infection from person to person? 6 What temperature should be maintained in the sick room in the treatment of (*a*) croup, (*b*) pneumonia, (*c*) typhoid fever? 7 Name the diseases regarded as quarantinable 8 Define food and name two which are in themselves complete or perfect foods 9 What are the legal obligations between physicians and patient? 10 What are the essentials of a thorough medical examination of an applicant for life insurance? 11 What constitutes expert medical testimony? 12 Name the post mortem signs external and internal of recent drowning 13 In signing a certificate of insanity what facts relating to the patient should be recorded? 14 Define a wound in its medicolegal sense 15 In witnessing a will, what facts should satisfy the physician as to the mental competency of the testator?

MATERIA MEDICA AND THERAPEUTICS

1 Name (*a*) the source, (*b*) the preparations, and (*c*) the effects of ergot 2 Differentiate the symptoms of atropin and morphin poisoning 3 (*a*) By what drug, and (*b*) by what method may local anesthesia be induced? 4 Explain the theory of the action of antitoxin 5 (*a*) Mention five preparations having antiseptic properties; (*b*) Give adult dose of each 6 Describe (*a*) the method of administration and (*b*) the results to be accomplished by the hot pack 7 State (*a*) the source, (*b*) the action, and (*c*) the therapeutic uses of strychnin 8 (*a*) What remedies may be used in septic condition of the alimentary canal? (*b*) Give dose of each 9 Outline a dietary in (*a*) chronic rheumatism, and (*b*) chronic interstitial nephritis 10 Write a prescription for any ailment in which iodid of potassium may be used 11 Specify (*a*) three official preparations of aconite; (*b*) adult dose of each 12 Give (*a*) the source (*b*) the physiological action, and (*c*) the infantile dose of santonin 13 (*a*) Prescribe in proper form for diarrhea in a child 4 years of age (*b*) Explain the action of each ingredient 14 Give (*a*) the therapeutic uses, and (*b*) the adult dose of terebene 15 Define (*a*) alteratives, (*b*) antipyretics, and (*c*) mydriatics

HOMEOPATHIC MATERIA MEDICA

Give characteristic indications for 1 Hepar in corneal ulcers 2 Aconite in facial neuralgia 3 Arsenicum iodid in coryza Compare 4 Causticum and bryonia in aphonia 5 Silica and aurum in bone disease 6 Nux and alumnia in constipation 7. Ipecac and natrium mur in malaria Name five remedies prominently useful and give the characteristics of one in 8 Skin diseases. 9 Typhoid 10 Acute nephritis 11 Apoplexy 12. What is a homeopathic prescription 13 Define the simillimum. 14 Give three essentials of a homeopathic prescription. 15. Give treatment for renal calculus.

OBSTETRICS AND GYNECOLOGY

1 Give a comparative description of the virgin uterus and the uterus after child bearing 2 State procedure in case the head refuses to engage the pelvic brim 3. How may rupture of the uterus complicating delivery be recognized? How should such a condition be managed? 4 Under what circumstances during labor may obstetric anesthesia become advisable? Mention an appropriate anesthetic and describe the method of administration 5. What may cause delay in the second stage of labor? How should such a condition be managed? 6 What are three most dangerous forms of uterine hemorrhage? 7 Outline your treatment of the foregoing types of uterine hemorrhage 8 Describe toxemia of pregnancy and state what may be done to prevent or to relieve this condition 9 Under what circumstances is induction of abortion permissible and how is it safely performed? 10 Name the varieties of salpingitis and give briefly the etiology and diagnosis. 11. What are the causes of pelvic abscess? Describe method of surgical treatment. 12 Mention the causes and state the management of cystitis in the female 13 Mention the prodromal symptoms of puerperal eclampsia Describe the management of puerperal eclampsia 14. Give the causes, diagnosis and treatment of prolapse of the ovary 15 What is ophthalmia neonatorum? How prevented? How cured?

PRACTICE OF MEDICINE

Differentiate: 1 Acute pericarditis and acute endocarditis 2. Apoplexy and acute alcoholism 3 Cancer and ulcer of stomach 4 Chancre and chancroid 5. Diabetes and acute glycosuria 6 Epilepsy and hysteria 7 Hemoptysis and hematemesis 8 Intestinal and hepatic colic. 9 Organic and functional heart disease 10 Pneumonia and pleurisy with effusion. 11 Pyelitis and cystitis 12 Scurvy and purpura 13 Typhoid fever and acute tuberculosis 14 Edema glottidis and retropharyngeal abscess 15 Cerebral concussion and cerebral compression

SURGERY

1. Give diagnosis and treatment of intracapsular fracture of the femur. 2. Give technic of posterior gastro-enterostomy. 3 Etiology and treatment of senile gangrene 4. Give causes, symptoms and treatment of phlebitis 5 Mention the causes of non-union of fractures 6 Give causes, diagnosis and treatment of abscess of the liver 7. How would you treat a penetrating wound of the trachea? 8 Describe acute suppurative osteomyelitis of the tibia 9 Gonorrheal arthritis; diagnosis and treatment 10 Differentiate between fracture of the neck of humerus and subcoracoid dislocation. 11. Discuss etiology of thrombosis. 12. Symptoms and treatment of acute pancreatitis 13. Diagnosis of floating kidney. 14. Mention the conditions that may necessitate amputation of an extremity. 15 Etiology and treatment of cystitis

South Dakota July Report

Dr. F. W. Freyberg, secretary of the South Dakota State Board of Medical Examiners, reports the written examination held at Lead, July 13-14, 1910. The number of subjects examined in was 13; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 32, of whom 26 passed and 6 failed. The following colleges were represented:

College	Year Grad.	Total No Examined.
PASSED		
George Washington University	(1908)	1
Rush Medical College	(1895) (1897) (1906)	3
Northwestern Univ Medical School	(2, 1909) (2, 1910)	4

Sioux City College of Medicine	(1896)	1
Bellevue Hospital Medical College	(1892)	1

The following questions were asked:

OBSTETRICS

1 At what stage can you make a positive diagnosis of pregnancy? Give findings. 2 Give the most important features in the management of a breech presentation. 3. Describe fully the indications for and the application of forceps 4 Describe the four most common positions of the fetus during pregnancy. 5 Give your treatment of a two and one-half months' pregnancy with adherent retroversion 6 How would you treat a labor, with child in normal position, inefficient, distressing pains having been in progress twelve hours, with no apparent dilatation? 7 What is adherent placenta and your method for removal of same? 8. Give directions for care of mother during the lying-in period 9 When should you repair a lacerated perineum? 10 With the head down on the perineum and severe labor pains with prospect of laceration, what is the proper method to pursue?

EYE, EAR, NOSE AND THROAT

1 Describe and give treatment for dacryocystitis 2. Discuss corneal ulcer, giving etiology, prognosis and treatment. 3 Define astigmatism, synechia, hypopyon, myopia, epiphora. 4. Diagnose and treat a case of (a) iritis; (b) pterygium. 5 Treat a severe puncture of the eyeball 6 Give symptoms and treatment of hypertrophied turbinated bodies 7 Give treatment for purulent inflammation of middle ear What dangers are apprehended? 8. Discuss the relation of adenoid vegetation and otitis media in children 9 Give four common symptoms caused by nasal obstruction. 10 Give anatomy of larynx and treat a case of laryngitis.

CHEMISTRY

1 Define an element, an atom, a molecule, chemical force 2. State the proportions of the chief constituents of the atmosphere What action is produced on air by animals? By plants? 3 What are deodorizers? Disinfectants? Antiseptics? Give an example of each 4 Give a test for sugar in urine. Determine the quantity by the fermentation test 5 Name three alkaloidal poisons Give antidotes.

PATHOLOGY

1 Define anemia, pyemia, bacteremia 2 Name the paths of bacterial infection; the paths of extension. 3. What changes may a simple (non infected) thrombus undergo? 4 Name the various degenerations, give examples of two 5. Give the pathology of phlebitis 6 Describe the changes in the pleura in the various stages of pleuritis 7 What is the pathology of Addison's disease? 8 Name the causes and give the morbid anatomy of acute poliomyelitis 9 Give the pathology of tuberculosis of the hip joint 10 What are antibodies?

DISEASES OF WOMEN

1 What are the sequences of gonorrhea on the female? 2 Vaginismus—name causes, give treatment 3 How do you treat endometritis? 4 Abscess of Cowper's gland—cause and treatment 5 Differentiate salpingitis and pyosalpinx; chancre and cancer of os uteri

SURGERY

1. Differentiate first, second, third degree burns and give treatment of each 2 Define, diagnose and give treatment of shock 3 Diagnose and treat post-operative hemorrhage 4 Give differential diagnosis of cholelithiasis, carcinoma of the stomach and duodenal ulcer 5 Diagnose and give treatment of fracture of patella 6

Diagnose and give treatment of Colles' fracture 7. Outline treatment of gunshot wound; point of entrance of bullet anterior portion of chest at eighth rib, right side, general direction inward and downward, no point of exit, patient conscious and in shock 8 Give treatment of lacerated and contused wound of scalp. 9. Give diagnosis and treatment of diffuse suppurative peritonitis. 10 What are the indications for, method of and location for paracentesis of thorax?

HYGIENE AND SANITATION

1 Describe an effective method of fumigation of residence following scarlet fever 2 Give rules for and length of quarantine for (a) diphtheria, (b) scarlet fever 3 Give method of transmission and management of case of typhoid fever for the protection of attendants and members of the family 4. Give practical method of caring for the garbage of cities with from five to ten thousand population. 5. Give in detail a method for the examination of water and milk supplies for the purpose of tracing the origin of typhoid epidemic.

ECLECTIC MATERIA MEDICA, THERAPEUTICS AND PRACTICE

1 Define the terms tonic and stimulant and give examples of each 2 Name three of the best alteratives and give dose of each. 3 Name three of the best diuretics and give dose of each 4 Give the specific indications for (a) lobelia, (b) pulsatilla; (c) hydrastis 5 Name three of the best intestinal antiseptics and give dose and method of administration of each 6 Give the specific indications for gelsemium, potassium iodid, muriatic acid; also dose of each 7. Diagnose and treat a case of diphtheria 8 Give differential diagnosis between alcoholism and hemiplegia 9. Give diagnosis and treatment of spinal meningitis 10 What do you know about "blood poisoning," its cause and treatment?

MEDICAL JURISPRUDENCE

1 How would you judge as to whether fracture of the bones of a dead body had been produced before or after death? 2 Define (a) illusion, (b) delusion, (c) hallucination; (d) dementia 3 Having found the body of an infant, give evidence of its having been mature, of its having been born alive and as to cause of death 4. In a partnership business of two physicians, to what extent, if any, is the one liable for the negligence of the other, in case of a malpractice suit? 5 What constitutes malpractice in a medicolegal sense?

PHYSIOLOGY

1 How is the normal temperature of the body maintained? 2. What is the omentum and what are its chief functions? 3 Give examples of proteins, and state how and where digested 4. What is the largest gland in the body and where is it located? 5 What is the average per cent of urea in normal urine? 6 What factors assist the heart in keeping the blood circulating? 7 What is lymph? Chyme? Chyle? 8 Locate and describe the parotid gland 9. Name the different varieties of cartilage and state where each is found 10 What are the functions of the spinal cord?

THERAPEUTICS AND PRACTICE (HOMEOPATHIC)

1 What is the chief sphere of action of gelsemium? Give characteristic indications for its use 2 Compare spigelia and cactus in heart affections 3 Give symptoms and treatment of gastric ulcer 4 Give indications for arsenicum in skin diseases 5 Diagnose and treat herpes zoster 6 Give causes, symptoms and treatment of cholera infantum. 7 Name two remedies with indications for their use in dysentery 8 Diagnose and treat membranous croup. 9. Name with indications two remedies for chorea 10. Compare arsenic, hepar sulphuris and tartar emetic in pus affections

SKIN AND GENITOURINARY DISEASES

1 Give diagnosis and treatment of herpes zoster. 2 Etiology, diagnosis and treatment of urticaria 3 Diagnosis and treatment of chronic infantile eczema 4 Etiology, diagnosis and treatment of erysipelas. 5 Symptoms, diagnosis and treatment of urethral stricture

ANATOMY, HISTOLOGY AND EMBRYOLOGY

1. Give histologic description of the section of the shaft of a long bone 2 Describe the shoulder joint 3 Give a brief description of the cerebrum, naming its lobes and fissures 4 Give histologic description of a section of the stomach wall, at the greater curvature 5 Describe the thyroid gland 6. Describe the male urinary bladder and give its relations. 7 Name the muscles of mastication Give origin and insertion of two 8 Describe histologically (a) striated muscle; (b) non striated muscle 9 Describe the wrist joint, giving arrangement of bones 10 What displacement occurs in a fracture of the lower one-third of the femur? Why?

REGULAR PRACTICE AND THERAPEUTICS

1. (a) Give causes, symptoms and diagnosi [illegible] tion; (b) give differential diagnosis between [illegible] and generalized peritonitis 2 (a) Define [illegible] give etiology; (b) give clinical history of the acute and chronic forms 3 Give differential diagnosis between primary lobar pneumonia and acute pneumonic phthisis 4 (a) Define uremia and give symptoms and treatment. (b) How do the symptoms differ in uremic unconsciousness and cerebral hemorrhage? 5. (a) Give symptoms of acute poisoning by iodid (b) When is iodid contraindicated? 6 (a) What is therapeutics? (b) Give rule of dosage for children (c) Name five modes of administering drugs 7 Give causes, symptoms, diagnosis and treatment of infantile convulsions. 8 (a) Give causes and symptoms of ascites (b) Give points of differentiation between ascites and chronic peritonitis (c) What is ascites most apt to be mistaken for? 9. Define the following: myalgia, pertussis, hemicrania, petit mal, acute chorea, tetany, neurasthenia, arsenicism, aphasia and anterior poliomyelitis 10. (a) What is a hematemesis? (b) Name five chief causes (c) What are the points of contrast between hematemesis and hemoptysis?

BACTERIOLOGY

1. (a) What are bacteria? (b) Describe the different forms. 2 (a) Give Neisser's method of staining (b) What is suspected when above stain is used? 3 (a) Give formula of the most commonly used stain for "acid proof" bacilli. (b) Give method of staining "acid proof" bacilli 4 (a) What are blastomycetes? (b) Where found? 5 (a) What is understood by lack of fermentation? (b) Where found? (c) What bacteria are most commonly found in lactic fermentation?

Book Notices

GYNECOLOGICAL DIAGNOSIS By Walter L Burrage, M.D., Fellow of the American Gynecological Society Cloth. Price, $6 Pp 656, with 207 illustrations New York. D Appleton & Co., 1910.

Burrage has endeavored to present in this new text a practical work written entirely from the clinical point of view, only the salient points of anatomy and the more recent views of pathology being summarized in each chapter. Like Winter's famous work, this text is divided into two parts, the first covering general considerations, the latter being special diagnosis. Clinical history and interpretation are considered in the first chapters, which include such general topics as menstruation, puberty, menopause, pain, constipation, etc. The physical examination of the patient is discussed at length in the succeeding four chapters.

In speaking of the barriers to the entrance of infective bacteria to the peritoneum, no mention is made of the influence of the normal vaginal flora. One short chapter is given over to the examination of the abdomen, the methods of which are excellently discussed, but the author limits his subject later to gynecology according to the strictest construction of that term. The relaxed abdominal wall, as a factor in female ills, is but incidentally referred to and the subject of enteroptosis is covered in a half page. Cystoscopy is gone into fully, and Kelly's method is described and freely illustrated. The first portion of the volume closes with a chapter devoted to the significance of the chief symptoms of pelvic disease, dysmenorrhea, intermenstrual pain, menorrhagia and metrorrhagia, amenorrhea, leukorrhea, dyspareunia, sterility, etc.

The author has devoted two-thirds of his work to special diagnosis. He notes the difficulty of classification of endometritis, and wisely makes no attempt to furnish one of his own. His description of pathology is surprisingly meager; here again the clinical point of view is in control. Burrage describes erosion as showing "no inflammatory action accompanied by destruction of the epithelium as in ulceration. The surface squamous epithelium, which normally covers the cervix, is removed—it is eroded—and the underlying columnar epithelium is hypertrophied." The author will have much difficulty in reconciling this view with that taught by the pathologist.

Pelvic inflammation, congenital anomalies, fibromyomata, and malpositions of the uterus are covered ably, while no fresh contributions are offered. The differential diagnosis, as elsewhere in the volume, is presented in parallel columns. Malignant disease of the uterus is considered clinically, but on a pathologic classification The importance of early diagnosis is emphasized, but here again the histopathology is vague. The author at one time speaks of chorio-epithelioma as being composed of placental tissues (villi) and at another as if it were identical with a placental polyp.

A chapter is devoted to the ovary, and one to the tube. Pfannenstiel's classification of ovarian tumors is accepted and the differential diagnosis is elaborated with special reference to the intraligamentous variety, torsion, and the results of infection. Extra-uterine pregnancy is exceptionally well described and illustrated, and the importance of differential diagnosis is properly emphasized. Diseases of the vagina, vulva, urethra, bladder, uterus and rectum are taken up adequately, each in a separate chapter, the author emphasizing his belief that the bladder and rectum are too often neglected. He includes a chapter devoted to diseases of the breast, based on Bloodgood's classification.

The gynecologic affections of infancy and childhood are wisely given a place, and such topics as vulvovaginitis, masturbation and enuresis are considered. A chapter on the menopause and old age concludes the volume.

Altogether it may be said that this work is a practical one for the general practitioner who is always most interested in the clinical side of his work. Its great fault, as has been noted before, is the lack of laboratory method as applied to diagnosis. Special text-books are lamentably weak on gynecologic pathology, and surely if there is a place for such minutiæ it is in a text devoted exclusively to gynecologic diagnosis.

Dislocations and Joint-Fractures. By Frederic J. Cotton, A.M., M.D., *First Assistant Surgeon to the Boston City Hospital.* Cloth. Price, $6 net. Pp. 654, with 1,201 illustrations. Philadelphia and London. W. B. Saunders & Co., 1910.

One of the most commendable features of Cotton's book is its originality. The volume embodies the results of the author's study and personal experience with a lot of material, and this lends to it a distinctive and unique value. There is a place in surgical literature for a book on joint-injuries, fractures and dislocations, especially since the *x*-ray in the last decade has caused many long-accepted views to be modified and revised. Every experienced surgeon will concede the importance of joint-injuries, knowing that permanent disability sometimes follows treatment by even the most expert. Dr. Cotton has covered this field of joint-injuries most completely; his style is clear and lucid, and the text is embellished by a great number of good original drawings and reproductions of radiograms. There is no question that it is of great advantage for the author to be his own artist, a circumstance which tends towards the elimination of unimportant details, and the accentuation of the essential features of a drawing.

In the chapter on "Generalities" are collected many facts worth knowing regarding fractures, and much sound advice and wise teaching. There are taken up in succession fractures and luxations of the jaw, spine, sternum, ribs, clavicle and scapula. Then follows a chapter on the shoulder, its various luxations, their mechanism and treatment, and the different varieties of fractures about the shoulder-joint. The elbow is given due prominence, with its anatomy, landmarks and luxations. The fractures about the joint are described clearly and in detail, and the value of the text is enhanced here as well as throughout the book by the profuse and fitting illustrations. In the same thorough manner the author treats of the wrist, hand, pelvis, hip, knee, ankle and foot.

Dr. Cotton preserves his equilibrium and keeps on an even keel throughout. There is no tendency towards dogmatism, nor are there any radical views expressed about treatment. His ideas about immobilization, massage, and passive motion are sane and moderate, and would be acceptable to the majority of surgeons. Every case of joint-injury is a study by itself, and the surgeon, in diagnosis and treatment, must apply those general principles underlying all fractures which he has acquired by years of study and experience. Thus he drifts away from the notion of treating all cases of a certain type of fracture with Dr. So-and-So's splint. Treatment is accomplished by the use of the simplest kind of retention apparatus. The author's attitude towards the operative treatment of fractures is that indiscriminate operating is uncalled for. He essays to teach that in some types of cases the fractures do best if operated on early; others do well without operation, if treated properly from the beginning. Proper emphasis is laid on the taking of *x*-rays after, rather than before reduction of a fracture, to control the position of the fragments before it is too late to reset. Faulty position is due rather to improper treatment than to errors in diagnosis.

The book deserves hearty acceptance by the general practitioner as well as by the surgeon. The paper is good, the printing is clear, and the bookmaking leaves nothing to be desired.

Genesis. A Manual for the Instruction of Children in Matters Sexual, for the Use of Parents, Teachers, Physicians and Ministers. By B. S. Talmey, M.D., Former Pathologist to the Mothers' and Babies' Hospital and Gynecologist to the Yorkville Hospital, New York. Cloth. Price, $1.50. Pp. 194. New York: The Practitioners' Publishing Co. (1910).

The author calls this "a manual for the instruction of children in matters of sex." It is intended to be put into the hands of teachers and parents, not of children. It consists, first, of matter going to prove the necessity for such instruction, and, second, of an outline of instruction intended to lead children's minds by various ways, chiefly through explanation of the phenomena of reproduction in the lower orders of life, gradually to a proper understanding of sexual physiology and hygiene in human beings. The general plan proposed is unexceptionable, but not original.

As a "manual of instruction," the book is not practical. The biologic facts presented are far too complicated and are described in language entirely too technical to be suitable for children. Very few teachers and still fewer parents would be capable of selecting, out of the many offered, the few essential facts and of presenting them in such simple form that children would be able to grasp them. In fact, the technical language might be rather appalling to a "grown-up" with no special training in science or interest in biology. Only a person with exceptional gifts as a teacher could really get much out of it.

A feature which should receive careful attention in a book intended for the instruction of the young in this subject is the proper coordination of the subject. The sexual physiology of plants, for instance, should be taught incidentally to the general subject of botany. The necessity for proper coordination has scarcely received in this book the emphasis it deserves. The possibility of giving an exaggerated perspective by taking facts out of their context is one which should not be overlooked. A book for this purpose ought to be written by someone possessing real knowledge of children and a practical acquaintance with educational methods.

Diseases of the Colon and Their Surgical Treatment. (Founded on the Jacksonian Essay for 1909.) By P. Lockhart Mummery, F.R.C.S., Jacksonian Prizeman and late Hunterian Professor, Royal College of Surgeons. Cloth. Price, $3.25 net. Pp. 322, with 88 illustrations. New York: William Wood & Co., 1910.

This monograph is founded on the Jacksonian Prize Essay for 1909. The book is well illustrated with figures in the text and inserted colored plates. It is exhaustive and up to date, and the author's expressions of judgment are sensible. For instance, he says, "The fact that human beings can live without a colon is, however, no proof of its uselessness and at present the evidence brought forward to prove that the colon is a useless and effete portion of the alimentary tract is anything but convincing." The first two brief chapters treat of the anatomy and physiology of the colon. Cannon, Elliott and Smith and Hertz are given credit for their recent interesting work on its physiology. The next chapters are on morbid physiology, bacteriology and diagnosis. The author has shown by experiments that if the colon is cleaned thoroughly it will not become distended with gas, which must be interpreted to mean that the gas causing distention is due to fermentation in the feces. Further on he says of postoperative meteorism, "I have never seen it, nor been able to find an instance of it except in cases when there were obvious possibilities of some infection."

Comment cannot be made on all the diseases of the colon discussed by the author. Mucous colitis the author believes to be a true inflammation, and not a neurosis. He bases his belief on numerous cases in which during surgical operation evidence of inflammation was demonstrable. Olive-oil enemas are recommended as the best medicinal treatment. Some cases persist in spite of all treatment, and for these surgical aid has been sought. The author's analysis of the various operations which have been resorted to is most interesting. He recommends appendicostomy, and the subsequent persistent washing of the colon through the appendix. He discusses such surgical procedures as have been resorted to in extreme cases and can approve only of washing the colon through the appendix, which gives relief and sometimes effects a cure.

The Ear and Its Diseases. By Albert A. Gray, M.D., Laureate of the Lenval Prize in Otology, International Medical Congress, 1909. Cloth. Price, $4.25. Pp. 388, with 123 illustrations. New York: William Wood & Co., 1910.

This is a compact book of 388 pages, bringing otology reasonably well up to the year 1910. The chapters on "Acoustics," "Anatomy and Physiology" are clear and well illustrated; and the chapter on "Methods and Principles of Investigation" is one of the most useful in the book, and clarifies the different aural tests (including those of Barany) so that an ordinary man can understand them. There is a practical chapter on "General Semeiology and Therapeutics," and a short chapter on "Nasal and Pharyngeal Affections," and then follow the chapters on the various diseases of the ear, which are good and comprehensive. The chapters on mastoid surgery are unsatisfactory and poorly illustrated. It really is a pity that a book containing so many good illustrations should be damaged by the presence of a considerable number of those old, crude and behind-the-times illustrations from Politzer and others. Mastoid surgery has advanced enormously since these old prints were made, and it is too bad to have them still appearing in modern text-books. The stereopticon pictures are a novelty, but their real usefulness might be questioned.

Second Annual Report of the Michigan Association for the Prevention and Relief of Tuberculosis for 1909-1910. Containing Statement of Work Accomplished—Report of Convention at Ann Arbor—Report of Local Associations—State Needs—Report of Secretary and Treasurer. A Brief of the Year's Work. Submitted by the Secretary, Aldred Scott Warthin, M.D., Ann Arbor, Mich., Feb. 26,1910. . Paper. Pp. 216, with illustrations.

This is a record of the splendid work done in Michigan against tuberculosis in 1909-1910. It is a strong appeal for substantial encouragement in the work, made by setting out graphically and forcibly the tremendous expense of this preventable disease and the resulting loss to the state in dollars as well as in lives. This pamphlet contains several valuable papers on the management and methods of eradication of the disease, with illustrations of tents and tent colonies for the outdoor treatment, as well as reports from the local associations in the state, and a synopsis of what has been accomplished in the way of state and local sanitary legislation. There are many suggestions that should be of value to other state associations pursuing this work.

Biology, General and Medical. By Joseph McFarland, M.D., Professor of Pathology and Bacteriology, Medico-Chirurgical College of Philadelphia. Price, $1.75 net. Pp. 440, with 160 illustrations. Philadelphia: W. B. Saunders Co., 1910.

The latter-day methods of attacking the problems of function and disease peculiarly emphasize the close relationship and importance of biology to medicine. Not only is this true as to cytology, morphology and the chemistry of the cells, but also as to the chemistry and functions of the body as a whole, the problems of infection, immunity, mutilation, regeneration, heredity and senescence, and the grosser phenomena of parasitology and parasitism, all of which are most essential to a modern understanding of the science of medicine and the most enlightened methods of curing disease. In this brief work the author has treated the subject in a way to be of the greatest value to students of medicine.

A Text-Book of Botany and Pharmacognosy. Intended for the Use of Students of Pharmacy, as a Reference Book for Pharmacists and as a Handbook for Food and Drug Analysts. By Henry Kraemer, Ph.D., Professor of Botany and Pharmacognosy, and Director of the Microscopical Laboratory, in the Philadelphia College of Pharmacy. Fourth Edition. Cloth. Price, $5 net. Pp. 888, with 2,000 illustrations. Philadelphia: J. B. Lippincott Co. (1910).

The botanical portion of this work has been rewritten, especially that bearing on the morphology and classification of the angiosperms. The addition of about forty pages treating of the microscopic analysis of the crystalline forms of some of the important plant constituents will be of value in the detection and study of these substances. The work has, moreover, been brought up to date by including the results of the researches published during the past two years.

The Extra Pharmacopeia. Revised by W. Harrison Martindale, Ph.D., F.C.S., and W. Wynn Westcott, M.B., Lond., D.P.H. Fourteenth edition. Morocco. Price, 12 shillings net. Pp. 1054, with supplement, Organic Analysis Chart, by W. Harrison Martindale, Ph.D., Pharmaceutical Chemist. Morocco. Price, 3 shillings 6 pence net. Pp. 80. London: H. K. Lewis, 136 Gower Street, W. C., 1910.

This volume furnishes in a convenient form a large amount of detailed information on pharmaceutical and medical subjects, especially in relation to articles not contained in the pharmacopeia. The new edition contains some important changes. New chapters are introduced on lactic acid bacilli, organic arsenic compounds, iontophoresis, radium, etc. Vaccine therapy, the Wassermann test, trypanosomiasis, examination of stomach contents and the flavoring of medicines are among the subjects discussed.

The Practitioner's Visiting-List for 1911. Leather. Price, $1.25. Pp. 192. Thirty Patients per Week. Philadelphia: Lea & Febiger, 1910.

"The Practitioner's Visiting-List" combines, in a neat pocket book, well bound in leather, a convenient record for the physician's visits and professional engagements, and much information that he is likely to need on his daily rounds, such as tables of doses, poison antidotes, etc.

Medicolegal

Construction of Medical Practice Acts with Reference to Certificates and Verification Licenses—Requirements for and Construction of Restricted Certificate.—Presumptions as to Acts of Boards.—Right to License

The Supreme Court of Texas says, in State Board of Medical Examiners vs. Taylor and wife (129 S. W. R. 600), that the latter parties sought by mandamus to compel the board to issue to Mrs. Taylor the verification license to practice medicine provided for by section 6 of the act of 1907. A district board of medical examiners had issued to her, in 1889, a certificate stating that they had examined her and "find her qualified to practice the branches of obstetrics and diseases peculiar to women and children, as required by the laws of the state of Texas." Under this she practiced medicine from its date, but the State Board refused any evidence of authority to practice, except a license to practice obstetrics only.

The provision of the act of 1907 above referred to requires the issuance by the present board of the "verification license" on production of documents sufficient to establish "the existence and validity" of the "valid and existing license heretofore issued by previous examining boards." What the verification license is to be the law does not expressly say; but its name and the purpose for which it is required plainly indicate that it is to be merely the evidence of the continuance of authority to practice as before, neither adding to nor taking from that authority. Pre-existing lawful authority is thus recognized and continued in force by compliance with the law. Therefore, if it was true that the first certificate was a valid license to practice medicine at all, either generally or in the branches mentioned in it, it must follow that the plaintiffs were entitled to a verification license to continue in force such authority as it had conferred.

The law formerly regulating the licensing of physicians, and which was in force when the certificate in question was issued, provided that it should be the duty of the board to examine thoroughly all applicants for certificates of qualification to practice medicine, in any of its branches or departments, on anatomy, physiology, pathological anatomy and pathology, surgery, obstetrics and chemistry, and when satisfied as to the qualifications of an applicant should grant to him a certificate to that effect, which should entitle him to practice medicine.

For the State Board it was contended that the certificate granted to Mrs. Taylor showed by its statements that the requirement that she should be found qualified in all those subjects was not complied with, and that it was issued on a finding by the former board that she was qualified only in obstetrics and in diseases peculiar to women and children, and that she was not qualified in the other subjects named in the statute. If it were true that the certificate showed all this, it would probably follow that the board so transcended its authority in extending a license of any character as to make its action void, since it was true that the statute did not admit any one to practice without the examination in all the prescribed subjects, resulting in the satisfaction of the board of the applicant's proficiency therein. But the court cannot say that the certificate meant that, consistently with the presumption that the board did its duty, which presumption must be indulged unless its action showed the contrary. The most that could be conceded was that a certificate so worded might be used to cover up a state of facts such as that which it was thus asserted to show affirmatively. It could not even be admitted that those facts would be fairly consistent with the truthfulness of the certificate, assuming the members of the board knew their duty. They said they had examined the applicant as required by law, which meant that they had examined her in all the named subjects and that they had found her qualified to practice the branches named. They could not truly have said that she was so qualified, in the sense of the law they were sworn to follow, unless they were satisfied that she possessed the knowledge required by that law of all the prescribed subjects.

All that rendered the certificate ambiguous or questionable was the mention of particular branches, and that might be explained by the fact that the statute plainly contemplated that there might be applicants who intended to confine their practice to particular branches or departments, which made it natural. and not improper, in such cases, to mention the branches or departments in the certificate, without restricting its meaning as to the scope of the examination and of the qualifications of the applicant. The statute proceeded on the conviction that qualification to practice in any branch or department could only be attained through adequate knowledge of the subjects named, and the court thinks it should be presumed that a board of medical gentlemen, selected because of their own proficiency, would proceed on a like conception, and would not issue a certificate affirming fitness to practice a branch without being satisfied themselves of the adequacy of the information of the person licensed concerning those things declared to be essential to that fitness.

The language, "When the board shall be satisfied as to the qualifications of an applicant, they shall grant him a certificate to that effect," meant no more than that the certificate should state that they were satisfied as to his qualifications to practice medicine, and a certificate in that language would have entitled an applicant to practice in all the branches or departments, or in particular branches or departments, as he might choose. The certificate in question, if the board understood their duty and spoke the truth, implied as full an examination and as complete qualifications as if it had been the more general one just instanced, since, under the statute, no one could be qualified, as was certified, to practice in the diseases peculiar to women and children without the required knowledge of the subjects mentioned. The provisions referred to did not apply to females practicing midwifery.

The question of whether the certificate entitled Mrs. Taylor to practice medicine generally, or restricted her to the branches mentioned, was not involved in this case. The State Board were not required to enlarge or diminish her authority, but only to issue to her a verification license to have the effect already explained. The judgment of the district court required them to issue only such a verification license as required by the act of 1907, "according to the provisions and wording" of the former certificate, and to that the Supreme Court thinks that the plaintiffs were entitled.

Liability for Negligent Communication of Small-Pox

The Springfield (Mo.) Court of Appeals had, in Franklin vs. Butcher (129 S. W. R. 428), a suit brought by a mother to recover damages for the alleged negligent communication of small-pox to her minor son. The defendant asked that the jury be instructed that the plaintiff could not recover unless she had proven that the defendant communicated the disease of small-pox to her son after he, the defendant, himself became aware of and knew that he was afflicted with said disease, and that he so communicated said disease by recklessly, carelessly and negligently bringing himself into contact with the plaintiff's son. Also, that the plaintiff could not recover unless the defendant wilfully or intentionally communicated the disease of small-pox to the plaintiff's son after the defendant had knowledge that he was afflicted with that disease. But the court thinks that these instructions were properly refused. If the defendant negligently and carelessly communicated the disease of small-pox to the plaintiff's son, it was immaterial whether it was done wilfully or intentionally, and it was also immaterial as to how it was done, if it was negligently done.

In the companion case of Hendricks vs. Butcher, decided on the same day (129 S. W. R. 431), the same court further says that it is familiar law that before an action will lie for negligence some duty must be neglected on the part of the party charged. But the court has no hesitancy in holding that any one afflicted with the disease of small-pox, which is known by every one to be a highly contagious disease, owes to every one the duty so to conduct himself as not to communicate this disease to them, after he becomes aware that he is afflicted with it. Hence, if the defendant knew that he was afflicted with small-pox, it then became and was his duty to keep away from other persons, or should other persons approach him, to notify them of the fact so that they might protect themselves.

Villages May Tax Occupation of Physicians

The Supreme Court of Nebraska, in reviewing the case of the Village of Dodge vs. Guidinger (127 N. W. R. 122), affirms the right of villages in that state to lay out and collect a tax on the vocation of a physician. The state statute gives authority "to raise revenue by levying and collecting a license tax on any occupation or business within the limits of the city or village, and regulate the same by ordinance." The defendant contended that practicing medicine is neither a business nor an occupation, but a profession; that, since the statute and the ordinance in question were silent concerning professions, the tax sought to be collected was void. But, in the court's opinion, a physician practicing medicine is engaged in an occupation within the meaning of the statute, and the plaintiff village under the legislative grant of authority had power to levy and collect a tax on the defendant's occupation or business.

Again, the defendant argued that the village might license only such vocations as it might regulate in the exercise of the police power, and that the practice of medicine was not subject to such regulations. But the statute authorizes the imposition of occupation taxes for the purpose of raising revenue. The taxing power, therefore, was the source of the village's authority to demand from the defendant the tax in question. The power of the legislature to raise revenue by levying a license tax on occupations is no longer an open one in Nebraska.

Removal of Garbage Controllable in Interest of Public Health

The Court of Appeals of Maryland says, in Schultz vs. State (76 Atl. R. 592), that it cannot be seriously contended that an ordinance which deals with garbage, house offal or other refuse, animal or vegetable matter, is not one which has a direct relation to the police power, or that it is not the duty of the city in the interest of the public health or comfort to assume the regulation and control of such matters. The fact that this accumulation contains fresh scraps of animal and vegetable matter does not prevent the extension of the police power of the city over the whole subject. More particularly, it holds that it was a valid exercise by the mayor and city council of the city of Baltimore of the police power vested in the city by its charter to pass an ordinance providing that no person, except employes of the city engaged in public work, or persons under contract with the city engaged in public work, should convey any garbage, house offal or other refuse, animal or vegetable matter through any street, etc., of the city, without having first obtained a permit so to do from the commissioner of health, and then only in the manner prescribed in said permit.

Western Surg. and Gyn. Assn., Chicago, Dec. 19-20.

SOUTHERN MEDICAL ASSOCIATION

Fourth Annual Meeting, held at Nashville, Nov. 8-10, 1910

The President, Dr. W. W. Crawford, Hattiesburg, Miss., in the Chair.

President's Address: Advances in Medical Education

Dr. W. W. Crawford, Hattiesburg, Miss.: It is not enough to say that there are a few good medical colleges, our full duty shall not have been discharged until we have witnessed the disappearance of the last inferior one. The proper adjustment of this question must contemplate a four-fold educative need: 1. The profession must be made to appreciate that an over production of medical colleges means an over production of poorly equipped physicians 2 The layman must be brought to realize that there is a difference in medical degrees, so that he may demand higher standards 3 State legislatures must be awakened to their responsibility 4 The medical student himself must be convinced that the best is not too good for him

Safeguarding Society From the Unfit

Dr A B Cooke, Nashville Vasectomy is not specified as the method of sterilization in the Indiana law, but its advantages over other methods are obvious Orchidectomy is a mutilating operation, and one of considerable gravity, yet I am persuaded that it should be recognized and specified as the only method permissible in rapists Human nature will never rise superior to the idea that this type of criminal merits punishment, and punishment of a character which will render a repetition of the crime forever impossible As a preventive, particularly in the south, where this evil is most prevalent and most abhorrent, the legal infliction of one such penalty would have a more salutary effect than many lynchings or even burnings at the stake While the foregoing remarks have been directed to habitual criminals, they are just as applicable to the larger class comprehended under the general term "defectives" or "degenerates" That the importance of this great question is coming to be generally recognized is evidenced in the fact that such widely separated states as Kansas, Delaware, Indiana, Connecticut, Michigan, and New Jersey have enacted laws regulating marriage, while Utah, Oregon, California, Connecticut and possibly others have followed Indiana's lead in legalizing the sterilization of criminals and degenerates It is yet too early to point to definite results from the operation of these laws But when the crucial test of time shall have been applied, I believe it is reasonable to predict that crime and degeneracy will be largely decreased and the world be correspondingly better and happier

DISCUSSION

Dr George H Price, Nashville This subject contains two principal ideas, namely, the restriction of marriage, or the throwing around marriage such safeguards and barriers as will prohibit and prevent, if possible, the reproduction of such individuals as are a constant menace to society It is a difficult matter to secure legislation because there has been a lack of uniformity on the part of the medical profession looking to this great problem of safeguarding the public, nevertheless the medical profession should be foremost in advocating restrictive measures

Dr Francis Dowling, New Orleans Physicians of the medical department of Tulane University have taken up this matter and have received letters from those who are interested in securing such legislation as will safeguard the public Some have suggested that gonorrhea and syphilis should be among the reportable diseases to boards of health like cases of diphtheria or scarlet fever The people of the State of Louisiana are already agitating this question

Dr John H White, New Orleans There is one difficulty growing out of the particular remedy advocated by Dr Sharp of Indiana for the class of defectives under discussion, and that is, the operation of vasectomy would be utilized by the roué as fitting him to practice his nefarious life without risk of being caught, and I believe that is a thing which should be carefully considered before resorting generally to this operation A law providing for this operation should guard against men voluntarily submitting to this operation for that very reason

Dr Jere L Crook, Jackson, Tenn The time has arrived when the medical profession should take active steps toward bringing about consummation of the ideas embodied in Dr Cooke's paper.

Dr Isadore Dyer, New Orleans In the last few years this question has been discussed as one of supreme moment in connection with eugenics I believe that professors of eugenics, criminologists and scientists, who are interested in the solution of this problem, are all satisfied that the aphorism of Oliver Wendell Holmes, that a man's education should begin with the education of his great grandfather, is very pertinent and that we ourselves for the sake of our own people should establish at least this one law of protecting our decendants from the possibilities to which they have been exposed in regard to criminals and defectives

Dr George H Price, Nashville, offered the following resolutions, which were adopted

Whereas, The medical profession of the South believes that its highest office is to prevent disease and its most sacred obligation to safeguard those interests of society on which health and happiness depend, and

Whereas We are convinced that those interests are seriously menaced by the utter disregard of the procreative function which characterizes the present system of managing criminals and degenerates, therefore be it

Resolved By the Southern Medical Association, in regular annual session assembled that the members endorse as wise and beneficent the laws of Indiana regulating marriage and providing for the sterilization of habitual criminals and other degenerates

Resolved That these laws be commended to the earnest consideration of state medical societies, with the suggestion that persevering effort be made to incorporate their principles into the laws of each state

Exophthalmic Goiter

Dr W D Haggard, Nashville The four cardinal symptoms of this disease, tachycardia, goiter, tremor, and exophthalmos, are unmistakable An acute toxic case presents high temperature, extreme restlessness, tumultuous heart action, sometimes up to 200, and nausea and vomiting which may become frequent and distressing There may be epigastric and abdominal pain It looks and is like a violent septic intoxication Active delirium, followed by stupor, precedes death In the four acutely fatal toxic cases that I have observed, the patients all had temperatures up to 106 F, shortly before the end In the chronic cases with exophthalmos the eye symptoms are important Surgical treatment has proved superior to any other It can be shown statistically to offer the best results, and at present early operation is the best treatment It is comforting to realize that the disease can be very generally cured if taken in time The very acute or advanced cases are very grave surgical cases The present surgical efforts are directed to decreasing the blood supply by ligation of the arteries and thus reducing the amount of secretion, or to lessening the amount of secreting surface by partial thyroidectomy Mayo estimates that one fourth of the patients *come for relief in a condition precluding anything but ligation*, whereas two thirds can have the larger lobe and isthmus removed without the ligation of the opposite superior thyroid artery Ligation is especially recommended by Mayo in cases hardly severe enough to require thyroidectomy The cases in which I have performed ligation, while few in number, have been satisfactory in the relief of the symptoms In two cases, it was employed simply as a preliminary step in the graduated *operation, but one of the patients was so much improved* at the end of four months that the removal of one lobe of the gland is apparently not required at this time If, at least, in one case ligation had been substituted for thyroidectomy, a death from postoperative hyperthyroidism might have been averted

DISCUSSION

Dr B L Wyman, Birmingham, Ala The medical treatment of hyperthyroidism has been practically a failure in the majority of cases, and in recent years I have referred my cases to the surgeon I would emphasize the importance of early diagnosis Some time ago I referred a patient to Dr Mayo I advised operation years ago, but the woman deferred it until I felt that a thyroidectomy was impossible, and even the operation of ligation of the superior thyroid, which was finally performed by Dr Mayo, did not result favorably The woman had a dilated heart when she went to Rochester, and hence the operation was not followed by a favorable result If we hope to accomplish anything in the treatment of hyperthyroidism, early diagnosis and prompt operation are absolutely essential.

Bones and Joints

Dr. J. B. Murphy, Chicago: When there is a lesion in the neighborhood of a joint which causes inflammation or thickening, or adhesion of the capsule, if the surgeon wants to overcome deformity the capsule must be dealt with as one would deal with bone or with any other inelastic material. The outer fibrous capsule has a feeble vascularity. It practically never becomes inflamed; it is never the seat of a primary lesion. It never becomes tuberculous. It has an inner lining which is known as the synovial lining. The surface is represented by endothelial cells which are arranged close to each other, and they seal up the surfaces of both the synovial membranes just as accurately as the epithelial cells seal up the surface of the skin. If surgeons are going to do work on joints, one of the things they must observe is that the joint has an enormous resistance against infection, and they must become the greatest respecters of this endothelial layer in all work that involves the surgery of the joints. The time to attack a joint is when Nature or the surgeon has artificially prepared the joint in rendering it immune against easy infection.

Ankylosis can be avoided in practically every case of acute infection of joints. The moment the practitioner speaks of draining joints that are infected, he is assuming responsibility for an ankylosis. In an infection in a joint, to save it from destruction, it is necessary to relieve the joint of tension and the products of infection. This can be done by aspiration. But one can give the patient more relief than a hypodermic injection by putting on Buck's extension and separating the pressing surfaces that are inflamed.

Education of the Specialist

Dr. E. C. Ellett, Memphis, Tenn.: The solution of this and other similar problems will only be fairly settled when the whole thing is put under the control of the national government. With the establishment of a national department of health it may be feasible to map out a course of study and hospital work which a man must complete satisfactorily before he can appear before the world as a specialist in any department of medicine.

Treatment of Trachoma

Dr. H. H. Martin, Savannah, Ga.; In order to effect complete cure in chronic trachoma, surgical and medical treatment must be combined as neither is sufficient in itself. Of the surgical methods the one which I have called the Coover method is the most satisfactory from all points of view. For local application a solution of copper sulphate in strength of from 5 to 10 per cent. has no rival, but its use must be begun soon after the operation, and continued for eight weeks. Any attempt to sterilize the sandpaper is troublesome, unsatisfactory and unnecessary if the conjunctiva be scrubbed with bichlorid of mercury after the completion of the operation.

Malarial Manifestations in the Eye

Dr. M. H. Bell, Vicksburg, Miss.: My observations are based on the symptoms found in thirteen cases of eye trouble due to malarial infection. Corneal ulceration was present in eleven cases, and two entirely distinct types of ulceration were noted. In seven cases the common dendritic ulceration was present, and in the other four the ulcers were of the simple round variety, which I have designated acute herpetic. The acute type of dendritic ulcer I have found only in an acute malarial infection, and it has always responded readily to appropriate antimalarial treatment in combination with the application of tincture of iodin to the ulcerated area, and the usual local treatment employed for any corneal inflammation. I have found this form of ulceration recurring at times, especially in cases in which the treatment of the malarial infection has been stopped in too short a time, and for the prevention of recurrence, I have always placed most reliance on small doses of arsenic continued for some weeks.

The Artificial Leech in Acute Mastoiditis

Dr. U. S. Bird, Tampa, Fla.: My experience includes nine cases. Clinically they were all instances of typical acute mastoid infection, middle-ear disease, high temperature, mastoid swelling, and pain. In every case the middle ear has been freely opened without relief. In all of the cases operation seemed indicated, and in one case the patient was sent to a hospital for that purpose. In some heat was used, but in most it was unnecessary after the leech. Calomel was given at first as a routine measure. Improvement was noted at varying intervals after leeching. At times it was immediate; it usually occurred the same day. In one case the leech was applied in the morning with temporary relief. In the evening the patient was suffering so much that he was sent to a hospital with instructions that he be prepared for operation next morning. Next morning he was feeling better; operation was postponed, and he recovered without further incident. In every case relief was permanent, no further active treatment being necessary.

Episcleritis

Dr. O. Dulaney, Dyersburg, Tenn.: There is no specific for this disease. Most good is obtained from constitutional treatment. One is always safe in administering mercury; the salicylates and alkalines, also the iodids play their part, especially in cases of specific origin. The best results are obtained locally by the use of mild sedative lotions, and by keeping the pupils well dilated with atropin sulphate. Hot applications should be frequently used, much depending on the severity of the disease. The ointment of yellow oxid of mercury is very efficacious, and an ointment of boric acid will often give good results.

The Heath Mastoid Operation

Dr. M. M. Cullom, Nashville, Tenn.: This operation is safer than the radical operation, as there is less danger of intracranial involvement following it. There is practically no danger of injuring the facial nerve. There is no injury to the hearing and the operation is often followed by marked improvement in hearing power. Suppuration diminishes rapidly and postoperative healing takes place sooner than after the radical operation. It can be easily converted into the radical operation, if desired.

(To be continued)

MASSACHUSETTS ASSOCIATED BOARDS OF HEATLH

Quarterly Meeting, held at Boston, Oct. 27, 1910

The President, **Dr. Henry P. Walcott**, Cambridge, in the Chair

Typhoid Fever

Dr. Charles V. Chapin, Providence, R. I. [For the Committee on Typhoid Fever]: We believe that there is a lack of control of typhoid at present, and we urge local boards of health to be more energetic. Cases should be reported, and should not only be filed, but the boards of health should show to the physician some evidence that his report has been considered as valuable, and among other methods the milk supply in each case should be investigated. Earlier diagnoses should be made and in order to be of assistance the boards of health should offer the physician proper aid in diagnosis, such as facilities for blood-tests, etc. Directions should be given by physicians to nurses how not to spread it. Disinfection and isolation are recommended, and the placarding of house, front and back. Special attention should be given to any member of the family who handles foodstuffs, and the spread by this means avoided. If isolated, some means of determining the termination of isolation should be announced, as, for instance, when the patient has had a normal temperature for two weeks, as results tend toward the opinion that in the large majority of cases no bacilli are excreted after a two-weeks' absence of fever. Except with carriers the above period appears correct, and their cases have no rule. Hexamethylenamin should be given as a routine treatment. When a simple bacteriuria only is present, the results of hexamethylenamin are marked; 0.3 gm., given three times a day, has been known to clear the urine in twenty-four hours. Occasionally painful micturition occurs following its ingestion and in that event it is wise to discontinue its use. It is valuable in carriers, but does not always effect a cure. Other preventatives to the spread of the disease are to screen privy vaults from flies and build them rat-proof. It is recognized that all over the world the diminution of typhoid follows the lessening of the number of privy vaults.

Our list of recommendations is: 1. Local boards should require reporting of cases. 2. State boards, and their local boards, should offer to physicians facilities for examination of blood and feces. 3. Each patient should be visited in twenty-four hours by an agent of the board in relation to the matter of isolation and disinfection. The disinfectants should be furnished free by the boards. 4. Local boards should investigate milk and water-supply of each reported case. 5. Houses should be placarded. 6. Patients should be isolated. 7. Hexamethylenamin, 0.3 gm. three times daily, should be given for two weeks after a normal temperature has continued. 8. The two weeks following a continued normal temperature is sufficient, except in those handling foodstuffs, when the rule should be four weeks. 9. Typhoid carriers should not be allowed to perform work requiring the handling of food material. 10. Typhoid carriers should be under the observation of boards of health and required to report monthly. 11. A case on a farm should require that the authorities in all places receiving a supply of food from the farm should be notified. 12. Protect all privy vaults. 13. Exterminate the typhoid fly.

DISCUSSION

Dr. George W. Fitz, Boston: It is a simple matter to compile recommendations; the real problem is to enforce them. It is questionable whether they should be left to the discretion of local boards; it seems rather that they should be mandatory. If this matter is left simply to the publication of this report, little will be accomplished. We should have legislation to cover the matter.

Prof. William T. Sedgwick, Boston: I believe that this committee should confer with the Massachusetts State Board of Health. Recognition of typhoid as a dangerous disease is the kernel of the whole matter. When this is done we can treat it as a contagious disease and a menace to the public health. There should be no politics in the appointment of health officers, and they should be recommended by well-recognized health bodies.

Cholera

Dr. M. J. Rosenau, Boston: Cholera has a way of its own which we do not understand. It smolders for years and then breaks out. It is pandemic at present. We know its causal agent and its method of spread, but do not know why the epidemics begin. It acts like a spark spreading to others and a conflagration occurs. It is very interesting to compare the present cholera situation with the last epidemic—that of 1892. When cholera spread from the Orient to Europe in 1892 and threatened to come to this country, President McKinley was prevailed on to order a quarantine of twenty days on all vessels, and extravagant precautions far beyond the needs of the case were put into operation. I think that those who know most about conditions were sorry that these extreme measures were taken. It is a good sign of the real progress made in controlling the disease that plans are being made and carried out now without fuss, and when it is stated that there is very little danger, people have faith in that assertion. In 1892, sanitarians called attention to the fact that if cholera should get into the United States there would be great danger of a water-borne contagion in such cities as Philadelphia, Chicago, Lawrence and Lowell. These cities have so improved their water supplies now that a great epidemic is practically impossible, and we are safe from any such danger of infection as was suggested in 1892. Cholera was once considered a water-borne disease, as was typhoid. It is perfectly true in certain definite instances that water has been a vehicle for its spread, but in most instances—as in typhoid—it is by contact. We are well guarded against cholera. Even if it should get in, with all the improved methods of sanitation we should not have any trouble at all with it.

DISCUSSION

Dr. C. V. Chapin, Providence, R. I.: What is the duty of a health officer when he receives a list of suspects from the government officials?

Dr. M. Rosenau: He should have a trained agent see the people twice a week for from two weeks to a month. The ideal plan would be to require the suspect to report daily, and should he fail to report, to hunt him up.

Poliomyelitis

Dr. Robert W. Lovett, Boston: The epidemic character of this disease has attracted the special attention of medical men. It is increasing in frequency in all parts of the world. In the five years ending 1904, 300 cases occurred. In the five years ending 1909, 8,000 cases were reported, of which five-sevenths were in the United States. This increase is too great to be affected by the claim that the increase is due to the fact of reporting being more often compulsory at present. Analysis of the facts at our disposal results as follows: Immigration has not kept pace with the increase of cases and so apparently is not a factor. Scandinavian immigration has not even kept pace with the increase of cases, and so its prevalence in Norway and Sweden has not been an influential cause. Passenger traffic has increased but not at all commensurate with the cases of infantile paralysis, neither by steam nor electric roads. Automobile traffic has much increased and may be found to be a factor. Seasonable elements on being considered are not of much aid, as fruit appears to be without influence, and dust with presence or absence of rain has equal value for and against its spread. In New England it has spread with absence of the usual precipitation and in the northwest it has spread in the face of unusual rain. The influence of insects is of difficult estimation and demands further study. The epidemics appear to come in two-year periods and this fact may or may not be of value in the study. River valleys seem to be more prone to invasions than coast towns, but with marked exceptions, as at Boston and New Bedford, Mass., often an epidemic is followed by immunity of a section, but this is open to exceptions.

The State Board of Health is about to investigate as to the greater or less prevalence of animal diseases concurrent with the spread of poliomyelitis, particularly in sections showing the disease in epidemic form. It is not certain whether the danger of communication is over after the acute stage is finished. It seems wise to require isolation and absence from school.

DISCUSSION

Dr. John L. Morse, Boston: Early diagnosis is impossible at present. No special symptom of throat, stomach, bowels, or any organ is valuable. I have not found sweating or prostration, and these two symptoms are more often absent. Diagnosis is not possible until paralysis appears, except in epidemics or in patients previously exposed. In atypical cases also, no diagnosis is possible, as the patient may have the disease and recover without diagnosis. In a colony of children at the seashore eight had similar symptoms and ten days later one child had partial paralysis; I have no doubt that all the cases were cases of this disease. Lumbar puncture is of no practical importance in the diagnosis. Hexamethylenamin is of no value after paralysis occurs, although it may be of use in the incubation period. After paralysis has set in it may still kill a few germs. The child should be isolated, but the length of time is uncertain. I should prefer boards of health to designate a given time of isolation, even if not correct. Most physicians do not wear gowns while visiting these cases.

Dr. Edward H. Stevens, Cambridge: We should seek to allay public unrest and so publish the facts that the people may not fear an epidemic of such proportions and results as to cause a panic.

MINNESOTA STATE MEDICAL ASSOCIATION

Annual Meeting, held at Minneapolis, Oct. 6-7, 1910

(Concluded from page 1833)

Re-Operated Colles' Fracture; Thrombosis of Mesenteric Vein

Dr. Arthur T. Mann, Minneapolis: The fresh Colles' fracture had been treated months before in the usual way. The result was a wrist with marked deformity and loss of motion. Four months later a good surgeon had undertaken to correct the wrist by an oblique incision through the radius of about 45 degrees, pushing the lower fragment downward and forward. When the splints were removed four and a half weeks later the position apparently was satisfactory. The fragment slowly returned to its original position or worse. Five months later I operated, making a curved incision through the radius, curving a little farther forward below than above in order to gain a little extension, as the fragment was rotated downward and forward. Retaining splints were kept on eight weeks before union seemed firm. The patient now shows, three months after the operation, that the line of the radius is excellent, with a slight loss in length from the original impaction, and that all wrist motions are much improved and still gaining. In the case of thrombosis thirty-six hours after childbirth, symptoms of obstinate constipation and moderate tympanites had come on. Cathartics and enemas gave some result, but the conditions gradually increased, especially the tympanites; no special pain, though the abdomen was a little tender, more on the right side than the left; only occasional nausea and vomiting. An indistinct mass the size of a small child's head was made out in the upper right side of the abdomen, tympanitic, only moderately tender. The stomach area seemed dilated to the level of the umbilicus. Diagnosis, obstruction of the bowels from some cause not yet clear. I advised operation at once. The entire small bowel was found dilated, the large bowel down to the splenic flexure enormously so, while it was empty and collapsed below this point to the anus. The transverse colon was the apparent stomach area and the cecum and ascending colon was the mass felt. The appendix was found stretched tightly about the root of the mesentery with its tip adherent well up on the left side of the mesentery, thus constricting its vessels.

Typhoid Fever With Perforation

Dr. George Douglas Head, Minneapolis: From a study of the 495 reported cases, I conclude, first, that mortality is lowest in persons up to 15 years of age and beyond 25 years; second, that the mortality is lowest (50 per cent.) where perforation took place in the first week and highest in the third and fifth weeks of the disease; third, that the earlier the diagnosis is made and operative relief is applied the lower is the mortality. Of the 133 operations, sixteen were performed within three hours of the onset of symptoms, with 50 per cent. of recoveries. Of the twenty-five patients operated on between three and six hours, 44 per cent. recovered. Of the twenty-two patients operated on between six and twelve hours, 20 per cent. recovered, and of those between twenty-four and forty-eight hours, 11.1 per cent. recovered.

Pyelography

Dr. William F. Braasch, Rochester, called attention to the fact that surgical diseases of the kidneys are now being diagnosed largely by the use of the Roentgen ray and the cystoscope. Although they are of much value independently, of late the tendency has been to use the two methods combined. Thirty radiographs selected from several hundred illustrated a variety of conditions and were shown to be of value in the diagnosis of the following conditions: (1) The normal pelvis. (2) Mechanical pelvic dilatation. (3) Inflammatory pelvic dilatation. (4) Deformity accompanying renal neoplasm. (5) Localization of stone within the kidney. (6) Differentiation of extra-renal shadows. (7) Cystic kidney. (8) Solitary kidney. (9) Congenital anomalies of renal shape and position. (10) Hydroureter. (11) Identifying ureteral obstruction. Attention was called to the fact that although these plates were frequently of great practical value in the diagnosis of the various conditions demonstrated, nevertheless we must add this data to the other data derived from the cystoscope and the Roentgen ray, as well as those obtained from the case history and physical examination. A diagnosis is to be arrived at only by combining the data derived from the various sources.

DISCUSSION

Dr. William J. Mayo, Rochester: Dr. Braasch has been too modest in his claims for pyelography. I have operated on many of the patients whose kidneys have been pyelographed by Dr. Braasch, and I would like to acknowledge my indebtedness to him for the accurate diagnosis which enabled me to plan my work in advance, which made the operation so much easier and added so greatly to the safety of the patient.

Pyelography tells the size of the pelvis, the exact situation of the kidney with relation to the ribs, etc., and as to whether or not the kidney is infected in cases of hydronephrosis. The operation can then be made from behind, laterally, or anteriorly, as space or other conditions may indicate. In stone in the kidney pyelography tells whether the stones are in the pelvis, in which case they are masked in the pyelograph, but if they are in the cortex, they will show outside the pelvis. In two cases, radiographs showed stones apparently in the right kidney, pyelography demonstrated that the shadows were not in the kidney at all, but outside of this organ, and operation showed them to be gall-stones in an outlying gall-bladder and of just the right density to give shadows, which is not often the case in gall-stones. Pyelography enables one to make a diagnosis of hydroureter and to determine the size and position, as well as the location of the stricture.

In the diagnosis of certain tumors lying in the region of the kidney, the method is of the greatest differential value, showing at once the position of the kidney. In the genito-urinary field, as in so many others, we find that direct inspection by means of cystoscopy, ureteral catheterization and pyelography are clearing up old obscure cases of supposed bladder disease and proving that such diseases are extremely rare, although bladder complaints are extremely common. These complaints find their source in tuberculosis, stone, stricture, tumor and other diseases of the kidney and ureter, in posterior urethritis, prostatic disease, diseases of the seminal vesicles, etc. From a surgical standpoint this method of diagnosis enables the surgeon to work from the plan of the master diagnostician.

Mixed Tumors of the Parotid Glands

Dr. E. S. Judd, Rochester: We have observed forty-one tumors in the parotid, four in the submaxillary, none at all in the sublingual. In twenty-two of our series of forty-one cases the tumors were in the right parotid. The majority of tumors occurred in the second decade. The youngest patient was 15 years of age, the oldest 71. Twenty-five of the series were females. Average duration was 8 years. One case in our series was of one month's duration. In nine of our series of forty-one operated cases, the endothelial element predominated. Five were sarcomatous, three mixed-cell tumors undergoing sarcomatous change, ten were recurring growths. Twenty-seven of these patients have recently been heard from. Twenty-four state that they are "perfectly well." Three have a local recurrence; two of these had predominating sarcomatous elements at time of operation.

Pulmonary and Circulatory Complications Following Surgical Operations

Dr. E. H. Beckman, Rochester: This report is based on 4,530 consecutive cases operated on in St. Mary's Hospital, during the first eight months of 1910. Mortality rate in this series was almost the same in both classes; six deaths in pulmonary and five in the circulatory. Ether was the anesthetic used. Local anesthesia with cocain in a few cases. In the series of 4,530 there were thirty-seven complications, most of them extremely mild. There were six deaths in the group of thirty-seven cases; and fifteen cases of pleurisy, most of them mild. One patient died after a splenectomy. In eleven, symptoms occurred in the first week; four in the second week. Twelve cases of bronchitis, all mild types, none fatal. Ten cases of lobar pneumonia, five of which were fatal. Two of the fatal cases were in comparatively young adults with simple operations. Both developed delirium tremens, and died of complicating lobar pneumonia. The other three were debilitated old men with arteriosclerosis. One of them was 69 years of age, operated on for carcinoma of the lip and glands. The second, 80 years old, was operated on for stone in the urinary bladder. The third, 65 years of age, was operated on for gall-stones, and carcinoma in the head of the pancreas. Twenty-seven cases of complication were related to circulatory system. Phlebitis seventeen, embolism six. Of the seventeen cases of phlebitis there were three of the right side, fourteen of the left. Thirteen cases followed abdominal operations, four extra-abdominal. Five were infected cases, two at time of operation; three mild wound infections developed later. All of the cases appeared in the second week. No deaths. Six cases of embolism, two cerebral, were both fatal. Three of the four pulmonary cases were fatal. One occurred on first day, one fifty-six hours after operation, two on the eighth day, two on the ninth. In only one case was there evidence of infection either at operation or at autopsy. Ages of patients, 35, 43, 45, 57, 60.

Sudden Death in Cardiovascular Disease

Dr. John Grosvenor Cross, Minneapolis: Sudden death in cardiovascular disease occurs from various causes: (a) rupture of the heart wall; (b) rupture of an aneurysm; (c) pulmonary embolism; (d) coronary narrowing or blocking; (e) direct pressure of the diaphragm upon the heart, from distended stomach or intestines; (f) heart-block syncope; (g) thrombus in the heart; (h) air embolism; (i) sudden lack of venous blood-supply to the right heart, as occurs in large hemorrhage, or after abdominal blows; (j) a large group of cases of sudden death occur in myocardial weakness, either acute (toxic or infectious) and chronic in the acute forms, the muscle fibers show cloudy swelling or even fatty change; in the chronic forms there may be fibroid patches or individual muscle fibers, showing cloudy degeneration or fatty changes. Syphilitic changes are also found. The heart-muscle may become exhausted by prolonged tachycardia, as in hyperthyroidism. Most of these hearts also show degenerative changes. Valvular lesions are only to be considered as a factor in cardiac weakness. The possibility of sudden death in angina pectoris, Corrigan's disease, Stokes-Adams disease, aneurysm, recurrent attacks of acute pulmonary edema, should be considered. Besides these, in the presence of thrombosis of systemic veins, and in septicemia, the likelihood of embolism must not be forgotten. Degenerative changes in the ascending aorta are generally accompanied by coronary involvement and may lead to sudden death. Acute or chronic myocarditis predisposes to a like end, in the largest group of cases, from failure of the power of heart contraction, when there is a sudden call for increased heart power. The reserve power of the heart and true heart competency is the essential thing to be determined in prognosis. In an estimation of such conditions, sphygmographic tracings of the heart and vessels, as well as blood-pressure measurements, are a great aid to careful clinical examination.

How Shall We Treat Appendicitis After the First Forty-Eight Hours?

Dr. J. E. Moore, Minneapolis: Physicians and surgeons are now quite unanimous in the opinion that all cases of acute appendicitis should be operated upon during the first forty-eight hours, providing proper facilities and a competent operator are at hand. Without these requisites the mortality is greater with than without operation. After the first forty-eight hours the infection has usually extended beyond the confines of the appendix, and the surgeon can only hope to assist Nature, for he cannot remove the whole of the infection. When the surgeon is called on the third, fourth, or fifth day and the patient is doing well with a temperature below 102 and a pulse below 100, what is his duty? The experienced operator should operate at once, but should be content to remove the appendix and establish drainage. The occasional operator should wait until Nature has done her best. When the surgeon is called late and the patient is doing badly, with a temperature above 102 and a pulse of over 100, it is his duty to operate at once because these are Nature's signals of distress, indicating that she needs assistance. The removal of the appendix and the establishment of drainage meets the indications. More than this is meddlesome surgery. When the surgeon is called late, when the whole abdomen is swollen and boggy, and a so-called general peritonitis is present, what is his duty? A helpful operation is surely indicated. Remove the appendix if it is in evidence, but do not make an extensive search for it. Make two or more incisions and drain both flanks and the bottom of the pelvis with large rubber tubes. Excessive breaking down of adhesions and irrigation of the abdomen do more harm than good, and experience has proved that they are not necessary. Do not cork up the openings with gauze and call that drainage. The position of the patient after operation is of little consequence, so he should be made as comfortable as possible. The pressure within the abdomen is about 16 pounds to the square inch and the pus is bound to follow the line of least resistance, which is out through the openings. Do not give cathartics after operation, as they interfere with Nature's efforts to bring about a cure.

Death Certificates

Dr. H. E. Robertson, Minneapolis: Rarely has this subject been dealt with among physicians as it deserves. The ideal state must record the birth, the diseases, and the causes and date of death of each of its citizens. The importance of the subject is not impressed on us in our medical education and we rarely hear it discussed in our meetings. Improper returns are often found: "Sarcoma" and "carcinoma" with no mention of location; "Brain fever" and "Lung fever," obviously obsolete terms; "Accidental injury" with no statement of the accident; "Cardiac embolus following operation," the operation not being indicated. Remedies are recommended as follows: First, provide for some instruction in the subject in our medical schools. Second, make more frequent use of clinical and laboratory tests in the study of our cases. Autopsies are far too infrequent. Third, use more care and thought in filling in the certificate. The standard form requires a "cause of death" and "contributing causes." These may often be determined by the following rule: When resistance has become so lowered by some definite recognizable disease that other definite affections ensue and the patient dies, then we have a cause of death in the first disease and a contributing cause or causes in those that follow. For example, in a subject of acute nephritis dying of bronchopneumonia, the cause of death is "acute diffuse nephritis" and the contributing or secondary cause is "bronchopneumonia." Fourth, frequent consultations are necessary between boards of health, other statistical bureaus, and medical associations in order to maintain a uniform standard and promote better working relations on this important subject.

Management of the Puerperium

Dr. Fred E. Leavitt, St. Paul: The routine use of ergot following parturition is of no demonstrable value. Asepsis rather than antisepsis is needed in the care of maternity patients—soap and water instead of bichlorid. Extensive lacerations can be repaired much better a few days after labor than at the time of delivery. Good results are obtained if properly attended to even after a week. For the main stitch, silkworm and not catgut ought to be relied on. In getting up after delivery, the most satisfactory results follow when patients are encouraged to resume their natural habits soon afterward. After practicing this method for several years, both in private and hospital work, the results are found most satisfactory. In the first place, the patient's strength is not dissipated by remaining passively in bed, the bed pan is dispensed with in bowel and bladder movements, drainage is favored by the sitting posture, involution is more rapid and more complete, displacements less frequent, etc. After normal labors the patient is encouraged to continue her accustomed habits as far as she is inclined, both as to eating and activities. Even on the first day she may be propped up in bed for meals, get up onto the commode, move freely in bed; the third day she may be up in a comfortable chair for an hour or two, the next day twice as long, and so on, so that by the end of a week she is able to be all over the premises. The assertion is made that no case of disability in women can be traced to too early rising after childbirth.

INDIANA STATE MEDICAL ASSOCIATION

Annual Meeting, held at Fort Wayne, Sept. 18-30, 1910

(Concluded from page 1837)

Malaria in Indiana

Dr. Ada E. Schweitzer, Indiana State Board of Health: There was a time when malaria was a veritable plague in Indiana. A short story of its ravages in the early days and of the ideas and practices of the pioneer physicians, demonstrates the remarkable efficiency of scientific preventive medicine, assisted, as in this case, by industrial and commercial interests. In addition to consulting the usual sources of historical facts, a letter was written to the physician longest in practice in each of the ninety-two counties in the state. Replies were received from only twenty-eight counties, but these were so distributed over the state that every section was represented. These twenty-eight replies do not by any means represent the total number of cases occurring in Indiana during the year. But they do furnish positive evidence that the disease has not been completely eradicated, as many physicians assert. The anopheles mosquito is to be found in almost every part of the state, and every patient, whether he imported the disease or acquired it here, is a source of infection. Hence, we have the two factors necessary to the spread of malaria. This paper is not written in the belief that malaria will ever again be prevalent in Indiana. The state is too well drained and the people are too progressive for that. But physicians should remember that malaria does exist in this state and not allow an incorrect, preconceived opinion as to its absence to influence their diagnoses in the occasional sporadic cases they are likely to encounter at any time during the summer or fall.

DISCUSSION

Dr. George D. Marshall, Kokomo: There is an idea that the anopheles mosquito is a rare one. I have been studying these mosquitoes for four years, and they are plentiful. I can go out and catch three or four of them any time I want to around Kokomo. The people do not recognize the anopheles as a mosquito. I had a case recently of a boy who had spent three months in bed from malarial fever and was being treated for malarial fever at the time. I was called in consultation and gave him quinin in solution and the fever began to disappear, although it comes back once in a while. I was called to see the boy's grandmother, who was vomiting and had a temperature of 103 F. There were mosquitoes there. A year ago a young man in Kokomo died from what I diagnosed as malaria; there was a difference of opinion, and the man was treated for tuberculous meningitis. There is a large family living in the house where this patient lived, and nearly all are ill. I found a mosquito in a shed in the yard where the children played. That's where they got the malaria.

Bacteriology, Pathology and Diagnosis of Typhoid Fever

Dr. W. Shimer, Indiana State Board of Health, read this paper, in which he formulated the following conclusions:

1. Typhoid bacilli are present in the blood of every patient ill with the disease. They appear in the blood with the fever and disappear with the return of the temperature to normal.
2. Typhoid fever is not a true bacteriemia, but is an overflow from the spleen, lymph-glands and bone-marrow.
3. The clinical symptoms of the disease are due to the invasion of the blood by the bacilli, their destruction there, and liberation of their endotoxins. These endotoxins cause degeneration of the body cells and the consequent pathologic physiology.
4. Convalescence and tissue repair begin as soon as the bacilli disappear from the blood.
5. Long-continued or chronic typhoid seems to be due to the persistence of the bacilli in the blood because of the low grade of immunity. Chronic typhoid can sometimes be cured by injecting killed typhoid bacilli.
6. Blood cultures seem to be the method by which we can make the earliest and most certain diagnosis of typhoid fever, for several reasons, e. g., because the bacilli may be in the feces without the patient having the disease; the bacilli appear in the urine rather late in the clinical course of the disease; the destruction of the bacilli in the blood stimulates the production of the agglutinins and other antityphoid immune substances, and must, therefore, appear in the blood before the Widal reaction is positive.

DISCUSSION

Dr. B. W. Rhamy, Fort Wayne: There is no doubt that blood culture is the best-known method of diagnosticating typhoid in the early stage. It is therefore to be deplored that the method cannot be utilized except by those in close proximity to a laboratory. The clot-culture mentioned by Dr. Shimer seems to offer a practical method for those who are at some distance from a laboratory, and no doubt could often be used to good advantage. This clot-culture is made from the clot which forms in the glass capsules in general use for sending blood to a laboratory for the Widal test. It would be necessary for the physician only to draw a well-filled capsule of blood, seal the tips of the capsule in the flame and send to the laboratory, with instructions to make the clot-culture in case the Widal test was negative. There is some difference of opinion among investigators as to the amount of blood necessary for the culture test. Some men advocate small amounts, as from 0.5 to 1 c.c., while others, and perhaps the majority, advise the larger amounts of from 5 to 10 c.c. or more. The reliability of the blood culture, as well as of the Widal test, depends on the stage of the disease and the severity of the infection. Duffy in 1905 gave an excellent illustration in his series of cases. In eighty-eight patients, of whom fifty-six had a temperature above 102 F., he got positive blood cultures in all fifty-six, while in twenty-three with a temperature of from 100 to 101 F., he got positive blood cultures in only ten. This evidently depended on the severity of the blood invasion with its consequent liberation of endotoxins. The advantage of the blood culture over the Widal test is in the fact that the blood in the first week contains the greatest number of bacilli, while the Widal test does not show until these bacteria have stimulated the agglutinating power of the blood. Veil (*Deutsch. med. Wchnschr.*, 1906) compares these two tests in his cases. In thirty-six cases, during the first week, blood cultures were positive in 78 per cent., while the Widal reaction was positive in only 50 per cent. Out of 110 cases during the second week, the blood cultures were positive in only 60 per cent., while the Widal reaction was present in 92 per cent. During the third and fourth weeks the blood-culture percentage steadily decreased, while the Widal percentage remained constant. From these figures, which I believe are a fair representation of the possibilities of the two methods, it seems to me that the blood culture and the Widal test should be used in conjunction in any given case, thereby obtaining a greater percentage of accurate findings, than by the use of one to the exclusion of the other.

DISCUSSION

Dr. B. V. Caffee, Terre Haute: Away from the larger cities it is hard to get culture media. About two years ago in the pathologic society in Terre Haute we demonstrated a method of taking blood culture from a medium which can be obtained in any country village. It is entirely inexpensive and, according to the author of the article describing this method—whose name I have forgotten—it is quite as good as bouillon. He takes ox-gall from the freshly slaughtered beef; he dissects out the gall-bladder, tying the end of it with a ligature, then draws the gall into a test-tube and sterilizes it. By that method, I have demonstrated the typhoid bacteria in blood that came from the ear of a typhoid patient in two cases, and it was shown to be accurate. It seems to me that this method is absolutely reliable, and that it would be an excellent thing when a person cannot get a culture medium, because it is very easy to get ox-gall and entirely without expense.

In regard to infection of attendants in typhoid hospitals, a great change has occurred in the last twelve years. Twelve years ago I saw a demonstration of the infection of typhoid nurses. I was at that time steward in one of the army hospitals at Porto Rico. We had two small regiments and a battery of artillery—less than 2,500 men. In August and September, 1898, we had in our one hospital 268 patients, the majority of whom had typhoid. Of the twenty hospital corps men who nursed these people, fifteen took typhoid; three of the remaining five had had typhoid, and so were immune. We had no protection against flies, no screens, and our water-supply was very bad. But when you compare that with the conditions in hospitals to-day, the difference is as darkness from light.

Dr. G. W. McCaskey, Fort Wayne: The making of blood cultures is within easy reach of every general practitioner. I have had a fairly large experience along this line of work, though I have not had much experience in typhoid, having been out of general practice for a good many years. Culture media can be obtained in small sealed tubes. I formerly used a tube which I devised myself, hermetically sealed, containing 50, 75 or 100 c.c. They can be used by anyone and can be kept in the office for a year. In getting the culture, all that is needed is a syringe. The physician must sterilize his own hands and the arm of the patient; the needle is then inserted, and a syringeful of blood withdrawn. Then the blood is sent to the laboratory. I use an ordinary hypodermic syringeful of blood. Every physician ought to use blood cultures in these cases; they are within easy reach. I have a case now which I think is very interesting. The patient, a woman, was taken ill 5 or 6 weeks ago suddenly, with severe intestinal pain, diarrhea and a temperature of 102 F.—irregular fever. In a few weeks the fever practically disappeared, but the hemorrhage kept up, with severe pain in the sigmoid. She was gradually going downward, but the temperature was normal. She was taken to the hospital and I thought that perhaps I had tuberculosis to deal with. I submitted some blood to Dr. Rhamy, who reported a positive Widal reaction. Meanwhile, the blood culture was developing, and I submitted that to Dr. Rhamy, and he found the bacilli. This patient was at once placed on autogenous vaccine, and improvement followed; the temperature is perfectly normal; pulse perhaps 85, and the patient is apparently convalescing. This is undoubtedly a case in which the typhoid ulcers were very deep and did not heal after the temperature got back to normal.

Dr. Frank B. Wynn, Indianapolis: One of the commonest and most perplexing situations confronting the general practitioner is to determine in the early course of a fever, whether or not he is dealing with typhoid. The young or the thoughtless practitioner sometimes makes a guess and later is obliged to retract his early diagnosis. The Widal reaction has been a help, but blood culture goes a step farther and permits still earlier diagnosis of the disease.

I think that many of us fail to realize that typhoid fever is not simply a disease of the intestines, but of various organs, notably the lymph-glands, bone-marrow and the spleen; in other words, the blood-making organs of the body. One of the important lessons taught by blood cultures is that the organisms may attack almost any part of the body. I have a case now in which the parotid is infected. Sometimes the tonsils are involved. Indeed, some assert that this is the point of first infection, but I still think that the intestine is probably the primary seat of infection, not the tonsils. The advantages of the blood cultures are: first, early diagnosis; second, the idea which they give of the general dissemination, the wide-spread potency of the disease; and third, it seems to me that these cultural studies will be of immense practical benefit to us in differential diagnosis. A case came under my observation in which during the first five days the patient was delirious, with ordinary clinical picture of typhoid minus the eruption on the abdomen. The blood cultures showed a growth that was so extreme that it was thought there must be some contamination of the medium. The blood was drawn again, and the second test showed that this man did not have typhoid at all, but was suffering from a streptococcus meningitis.

Dr. E. Schmauss, Alexandria: I have not seen a case of typhoid in which extensive ulcers of the intestinal tract were not present. I have never seen anything diagnosed as typhoid which did not involve the intestinal tract. Now, the statement made by Dr. Wynn, that in typhoid we have an involvement of the whole body, is, of course true, but I dislike to allow the inference to be drawn that typhoid is not a disease of the intestinal canal primarily, and only secondarily involving the entire system. We would not claim that pneumonia is not a disease of the lungs, or that meningitis is not a disease of the brain, because we find the infective material in other parts of the body. I think we can safely say that typhoid is primarily a disease of the intestinal tract. It is said by some that the tonsils are the primary seat of infection. If this keeps on the tonsils will be held responsible for every ill of the body. No doubt many of our systemic diseases originate in the tonsils, but I think it is too far-fetched to say that the tonsils are the seat of typhoid fever infection. It is stated that the mortality has been reduced to 4 per cent. from 18 per cent. by the use of antitoxin. I have in mind an epidemic in a city, with 400 cases, in which the total mortality was 6 per cent. If these men had 18 per cent., it simply shows that there was misunderstanding or lack of care somewhere. There is no excuse for showing a mortality of 18 per cent., or anything above 10 per cent.

Dr. C. S. Bond, Richmond: It is a mistake to make a positive diagnosis the first time one sees a patient. Since the Widal reaction comes relatively late in the course of the disease, it makes it all the more necessary to be careful in the diagnosis. Some time ago I saw a patient in consultation. A little girl came home from a school where there had been a great deal of typhoid, and the physician took it for granted that she had typhoid fever. She had a temperature of 102 F., and she said she had some rose-colored spots on the abdomen. The patient kept going down for two or three weeks, and finally the physician found a little lump in one side of the abdomen. I had the case about six weeks afterward and found a tuberculous mass in that side of the abdomen; and the girl died of tuberculous peritonitis. This physician had made a diagnosis of typhoid fever before he had an opportunity to determine whether the girl had typhoid or not.

Dr. Albert Sterne, Indianapolis: I want to call attention to those cases which are not atypical, but which at the same time do not permit of accurate diagnosis except with the assistance of complete blood examination, cultures, Widal test, etc. That is the kind of typhoid I see, and not infrequently, either. These cases begin with the symptoms of an ordinary depressant insanity—confusion, sometimes marked delirium, with evidences of brain agitation. There is very little fever—in fact, almost no fever in the beginning; slight rise of temperature in the evening, but hardly more than in the normal state. The mental confusion is not delirium or ordinary mania, it is an ideation which, while more rapid than normal, savors of the fixed rather than the rapid ideation which appears when there is inability to express an idea by word of mouth. In these cases I frequently test, not the blood, but the spinal fluid. It is in such cases that laboratory methods of diagnosis are necessary. Diagnosis is practically out of the question without them.

Dr. John C. Fretz, Deedsville: The statement was made that it was inexcusable for a physician to lose more than 10 per cent. of typhoid cases. I do not know any man who has lost 10 per cent.; but who has the right to say what percentage a man may lose? I do not want an expression made in this society to go out over the state and to the laity that a man has no right to lose more than 10 per cent. of his typhoid patients.

Dr. A. P. Buchman, Fort Wayne: In diphtheria we have an absolute specific, and that specific is so harmless that its use cannot do the patient any harm. In typhoid fever we have nothing of this sort. It is the individual patient whom we have to look after, and the man who has a reasonable amount of experience and knows how to get the history of his case, in seventy-five out of eighty cases can make a diagnosis of typhoid fever that is reliable within from 2 to 5 days of the inception of the disease—if he watches the patient closely and watches the symptoms. The five cases that are left are the cases for which we need the laboratory; but the idea that by means of the laboratory one can make a diagnosis, without symptoms and without a history of the cases is absolutely fallacious. The tendency is to laboratory mania. The Widal test does not always occur within the same time. In some of the carefully watched cases the test did not show the disease. There was something wrong somewhere. I feel confident that in time these tests will become more reliable, but the practice is in its infancy, and the man who talks about absolute certainty is wrong.

Dr. W. Shimer: This subject of typhoid seems old, and yet I think one of the biggest problems we have in America is that of control and eradication of typhoid fever. Robert Koch at his death was trying to solve this problem for Germany. Any culture medium in which typhoid bacilli will grow is good to use. The main thing is that it must be absolutely sterile. One can use ox-gall, broth, anything. The Epstein medium is of special value because it can be carried in a small tube in the pocket. If it is not taken to the laboratory for 12 to 24 hours, the bacilli will grow in the solution.

The difficulties of taking the blood have been magnified considerably. I have done it often within 5 minutes. Dr. Simonds and I at the State Bacteriologic Laboratory have often drawn from our own veins from 10 to 15 c.c. of blood, and never put any bandage on. It is the easiest thing in the world, especially in people who are somewhat spare. Put the needle into one of the large veins of the elbow, and when you get through just pull out your needle. It is as easy as a hypodermic injection. Accuracy is absolutely necessary, and lack of it means contamination. Often surgeons, who know so much about asepsis, will bring in fluid full of bacteria, and yet they think they have been extraordinarily observant of asepsis.

Many instances have been reported of discrepancies between positive and negative findings in blood cultures. A large number of cases are necessary for conclusions to be of value. Coleman and Buxton had pretty nearly 2,000 cases. The German army statistics, which show from 12 to 18 per cent. mortality, were the average of a large number of cases. One cannot draw conclusions from the experiences of a man in general practice or in a small hospital. There seems to be some misconception of the difference between serum and vaccine. A therapeutic serum is a serum from an animal that has been inoculated with a specific bacterium, and a vaccine is made from the dead bacteria; both are injected to produce immunity to the specific organism in question. They are, however, entirely different preparations.

Plea for Cesarean Section, Based on a Report of Fifty-Three Operations Performed in Indiana

Dr. G. W. H. Kemper, Muncie: Formerly this operation was regarded as the *dernier ressort* of midwifery. In other words, after the unfortunate woman had been subjected to efforts at delivery with forceps and version, and reduced to exhaustion, and the fetus subjected to injuries, the abdomen was incised, and if death resulted to mother or child, or both, it was attributed to the Cesarean section. It was like the early beginning of antitoxin, which might be tried for diphtheria after all other remedies failed, and then incurred the blame for a death it did not cause, and declared to be inert or harmful when it had not been given a fair test. I have collected from various operators, fifty-three cases of Cesarean sections done in Indiana. The first case of which I can find a record was performed near Madison, Jan. 29, 1863, and the last, August 20, 1910. The following is an analysis of the fifty-three cases:

	Cases.
Mother and child saved	27
Mother alone saved	11
Total number of mothers saved	38
Mother and child lost	7
Mother alone lost	8
Total number of mothers lost	15
Child saved with mother	27
Child alone saved	8
Total number of children saved	35
Child lost with mother	7
Child alone lost	11
Total number of children lost	18
Total number of mothers and children saved	73
Total number of mothers and children lost	33

I would not inculcate the idea that the physician is to open the abdomen rashly. The responsibility should be divided with one or more competent advisers. In the language of Oliver Wendell Holmes:

"The woman about to become a mother should be the object of trembling care and sympathy, wherever she bears her burden or stretches her aching limbs. God forbid that any member of the profession to which she trusts her life, doubly precious at that eventful period, should hazard it negligently, unadvisedly, or selfishly."

Conservatism of Elective Cesarean Section

Dr. O. G. Pfaff, Indianapolis: In obstetrics conservatism has ever been the dominating spirit. Parturition has been for ages venerated as one of Nature's processes, complete and perfect in itself, and until recently was surrounded by a sort of mystical halo which repelled all tendencies toward interference with the operations of its sacred laws. I wish here to refer to three cases very briefly. All patients were operated on at St. Vincent's Hospital. In one case, a woman with interstitial pregnancy was operated on at six months; the mother made a prompt recovery. In the second, at full term after more than twenty-four hours of violent labor with many attempts at forceps extraction, both mother and child were saved without any complication in recovery. The third patient was in labor all day and far into the night. The pelvis was deformed—less than three inches in the transverse diameter. The patient was taken to St. Vincent's Hospital. The membranes were intact and she had not been violently handled. The operation was done quickly and for several days everything looked well. On the fifth day there was rise in temperature and pulse-rate. The wound appeared to be in perfect condition. The symptoms increased and the next day the wound was again examined and found to have opened; the omentum presented at the upper angle. The catgut had evidently been absorbed early and the peritoneum and deep structures had retracted, allowing the omentum to become a wedge, which gradually forced its way to the surface. I resutured with catgut and reinforced the entire wound with silk-worm gut. However, the cavity had already suffered infection and the woman died. The death is probably chargeable to a surgical accident such as might occur in the simplest abdominal section, and bears no relation at all to the specific cause for which the woman was operated on. The child is alive and well. My conclusions are these: Elective Cesarean section is one of the safest of major operations, being favorably comparable with the interval operation in appendicitis. that is, it shows a mortality conservatively estimated at 3 per cent. or less when performed by capable surgeons in well-equipped hospitals. This low mortality by no means excuses unnecessary operations, but it certainly justifies us in undertaking this procedure for various indications not heretofore considered valid. When experienced judgment decides that a debilitated, poorly equipped woman is to encounter any serious danger in natural delivery, Cesarean section is the safest course. It is the best course in grave albuminuria before the onset of labor, or in placenta prævia immediately on recognition of the condition. Whenever through a deformed or narrow pelvis, or one obstructed by any growth, or because of an unusually large child natural delivery is impossible, section is the only humane procedure. Cesarean section is purely and exclusively a hospital operation and is to be placed on a firm basis through a careful study of the work of those experts who in our large maternity hospitals are devoting their lives to the development of this most beneficent and truly conservative procedure.

DISCUSSION

Dr. Walter Schell, Terre Haute: I agree with Dr. Kemper that Cesarean section should not be a matter of last resort. It is as difficult to make a proper high-forceps application as to do any operation within the realm of surgery, and the reward should be proportionate. Any man who has ever performed Cesarean section—any man who is capable of performing this operation properly—is competent to do anything that any other surgeon can do, therefore he should have a proportionate recognition of his knowledge and skill If a man is a properly trained obstetrician he should know in advance that in a given case he will probably have trouble, and he should know within relatively narrow limits the kind of trouble he is going to have Every woman who engages a physician for confinement has a right to expect of him the very best service and knowledge It should never be necessary for a physician to go to an obstetrical case without having seen the patient before In the past, physicians hesitated somewhat to perform this operation quickly and promptly, and this delay in the extraction of the child, and delay in placing themselves in position to control hemorrhage was one of the reasons for the immense mortality This operation received a new impulse and new life and took on new surgical aspect after Sawyer demonstrated the absolute necessity of gradually closing the wound in the uterus

The question whether Cesarean section is safer than the forceps or traction operation depends on the character of the forceps operation In a high forceps operation in which the pelvis diameters are less than 10 cm, and the child above average size, then wounds may be inflicted on the woman that may result, if not in death, at least in making her a cripple for the rest of her life I feel that the high forceps operation is an exceedingly difficult one

Dr M F Porter, Fort Wayne It has been years since I have consented, nor will I ever again consent, to doing a craniotomy on a living child, unless it is a monster or some thing of that sort I do not think that I have any right to do it I know that I can deliver a woman by Cesarean section and give her a better chance for life than I can by high forceps application I think that this line of surgery has been very much neglected More than half of the mothers are delivered without the presence of a physician, and yet when a woman comes out of labor she comes out under conditions that make it necessary for her to undergo inherent risks far greater than she would undergo in any ordinary surgical operation

In a large percentage of high forceps deliveries the child is seriously injured, 50 per cent of these children so injured are injured permanently, 30 per cent subsequently become epileptics, 20 per cent of the children in the Indiana School for the Feeble Minded are there because of a high forceps operation In the light of these facts we must stop in large measure these brutal so called operations, for they are brutal The maternal morbidity after this operation is as great as after Cesarean section done by an intelligent hand and under proper circumstances So far as the morbidity of the child is concerned in such cases, no man can deliver a woman and give the child as good a chance by ordinary delivery as by Cesarean section The risk to the child is infinitely less than by ordinary normal labor

Dr Joseph N Study, Cambridge City: I think it is time that physicians throughout the country knew more about this important subject What is to be done for the women so situated that they cannot have the advantage of a hospital, and who are seen at a time in their confinement when they can not be taken to a hospital? It is true that the high forceps operation injures the child, and in many cases causes feeble mindedness, but a physician is frequently called to a case in which labor is well advanced, something must be done immediately In such circumstances, if the child cannot be born through the natural passage without reducing its head, it seems to me proper and just that craniotomy be done, if the child cannot be delivered by forceps or otherwise

Dr F A McGrew, La Porte I want to place on record an unusually interesting and unique case of Cesarean section by accident The patient was a young woman, healthy and vigorous, a farmer's wife Within two weeks of confinement, while she was sitting in the kitchen, her brother, sitting about ten feet away had a shotgun across his knees and was cleaning the barrel The gun was discharged and the full force of the shot entered the woman's abdomen The whole front of the abdominal wall and the front and upper part of the fundus of the uterus were torn away The placenta was also torn loose, and the child was half expelled into the outer world; the buttocks and back of the child protruded from the abdomen The woman walked into another room to her bed, where she lay down and was covered up with the ordinary bed clothing About an hour later an operation was undertaken on an ordinary kitchen table, and the house was none too clean The woman's condition was much better than might have been expected She was pale and somewhat anemic, but the pulse was fairly good and she was a woman of great nervous force She stood the operation well The child was extracted—dead, of course—the uterus was removed and the stump fastened against the lower end of the abdomen roof against the peritoneum, so that drainage could be instituted Three or four days later the patient was removed to a hospital, in order to have the benefit of a trained nurse and better attention She recovered without incident However, about six months later I was compelled to operate for intestinal disturbance, and on opening the abdomen I discovered that the cervix and peritoneum, where they had been fastened together had drawn out into a band which was the cause of the intestinal disturbance The band was severed the intestine was in good shape The woman once more recovered without complication, and she is now in good health, and doing her own work

Dr E Schmauss, Alexandria. In the last case reported I see no use in bringing the cervix stump up to the peritoneum It could have been drained through the vagina In the case at St Vincent's Hospital, the defect in suturing was undoubtedly due to hasty work So long as the mother is in good condition and the child is alive, there is no need of haste, and if this patient had been carefully sewed up and adhesive strips had been put on, this accident would have been avoided One of the hardest things to decide in these cases is when to perform the Cesarean section in preference to the high forceps operation It is not so much the question of the living child as of the laceration of the mother

Dr Paul Martin In expert hands the maternal mortality rate for Cesarean section is less than 2 per cent, the fetal mortality is *nil*, and if we undertake always to do an elective Cesarean section rather than that of emergency, I am sure this rate can be very much reduced In general in contracted pelvis the fetal mortality rate is 20 per cent, from forceps it is from 35 to 60 per cent, by inducing labor, the rate is 30 per cent There are certain other cases, simply a slight narrowing of the pelvis, or a rigid, hard cervix and unyielding soft parts, which may be directly responsible for incompetency for normal labor This should be recognized, and early conservative methods adopted Cesarean section affords less risk to the child than the other methods or delivery, and perhaps equal chance to the mother of a healthy life I believe that to day the morbidity of the mother and the fetal mortality in the results which we get, are due to the inefficient application of the forceps, and the dangers of the applications of forceps I do not think can be over estimated

Differential Diagnosis of Labyrinthine Suppuration and Cerebellar Abscess

Dr John J Kyle, Indianapolis The observations herein advanced are the result of the study of Neumann's work on cerebellar abscess, and my own personal observation of the work of Barany at the General Hospital in Vienna on nystagmus and its value as a diagnostic factor in labyrinthine and cerebellar diseases The conclusions of Neumann are as follows

> It therefore follows if it is allowable to draw any conclusions from the certainly small number of cases that in the acute cases labyrinthine suppuration plays no rôle in the origination of cerebellar abscess but that the latter is set up either through the instrumentality of a sinus phlebitis or an extradural abscess of the posterior fossa An entirely different picture is presented by the chronic cases in the majority of which the cerebellar abscess is of labyrinthine origin and the path of conduction is more often the aqueductus vestibuli

To recapitulate the symptoms of circumscribed suppuration of the labyrinth, we have acute or chronic suppuration of the middle ear, deafness, pain in the ear, variations in tem perature, giddiness, disturbances in locomotion, sometimes facial paralysis, with marked probability of meningitis or abscess of the brain, or sinus thrombosis. In cerebellar abscess from internal ear suppuration—and they are usually associated—we have pain in the occiput or forehead, hemiparesis on the affected side, spontaneous nystagmus sometimes to the affected side, tendency of the patient to lie on the diseased side, disturbance of speech of a bulbar character, stiffness of the neck muscles on the affected side; the patient will support the head whenever any movement is necessary; nausea and vomiting are present and, in extreme cases, convulsions, muscular depression of the abdomen, Cheyne-Stokes respiration, and delirium. The nystagmus, either spontaneous or induced, will be to the side of the lesion. Differential diagnosis of course must be made between temporal lobe abscess, meningitis and sinus thrombosis. This may require surgical exploration, which should be advocated. In the 196 cases reported by Neumann, 25.98 per cent. of the patients were cured.

DISCUSSION

Dr. G. W. Spohn, Elkhart: I hold that there would be no abscess without a discharging ear—a chronic discharging ear. It is rare to have abscess of the brain from acute suppuration of the ear. Whenever the labyrinth is affected in any way, there is nearly always nausea and dizziness. When there is fistula from a bony condition and not from a membranous condition, we do not have suppurating labyrinthitis, but serous labyrinthitis. When there is dizziness and nausea, infection of the labyrinth is present. These symptoms will last for from 2 to 6 days, but generally only from 3 to 4 days, and of course no one can operate while the acute condition exists. Very seldom does brain abscess follow labyrinthitis. Abscess of the cerebellum goes almost directly to the sinus of the posterior fossa. To differentiate between the two: When we get stiffness of the neck, a discharging ear, no dizziness, no nausea, that will eliminate the labyrinth. If there are stiff neck and soreness right over the cerebellum, it is abscess of the cerebellum. A stiff neck points almost directly to the cerebellum or the posterior fossa. Few of these cases of acute middle-ear suppuration end in abscess of the brain.

The Hygiene of Menstruation

Dr. Jane W. Ketcham, Indianapolis: Healthy women should be able to follow their usual occupation during their menstrual periods. It is amazing how many women live in poor surroundings; they have just enough vitality to get along. If the general conditions in which these women live be improved and their well-being brought a little above par, so that they have enough vitality to spare for any unusual drain their menstrual difficulties will disappear. Good ventilation, warm clothing, regular habits—including sufficient sleep—and food of the plain and wholesome kind are of great importance. The patient must have outdoor exercise every day, regardless of the weather.

The less medication the better. The time to give medicine is between the menses, and then the medication should be tonic and alterative. Alcoholic beverages should not be given for the relief of pain in this condition. There are other drugs which are infinitely more desirable. The Russell Sage Foundation, which has for its aim the study of sociologic conditions, has reported that in New York City one woman in every four is a wage-earner. This is a larger proportion than is commonly supposed, and moreover, it is a condition which is not confined to New York City. This includes of necessity women of various classes, conditions and ages. Are they undermining their own health, or are they building it up? Are they endangering the health of the next generation, or will they transmit a tougher fiber? The economic importance of this question is on the increase from day to day, since the number of women who work is everywhere increasing.

DISCUSSION

Dr. J. M. Dinnen, Fort Wayne: I have been impressed with a serious error that has been made in this variety of cases, and that is the constant meddling with these conditions. I do not believe that any girl arriving at the age of puberty should be submitted to an examination without mature deliberation. I think all the conditions surrounding the patient should be taken into consideration, her habits of life, her mode of living, her surroundings, for I believe that enters more largely into the conditions at that time than anything else. The school girl is engaged at times with social duties, and few of them will cut out the social duty on account of the menstrual condition. I believe that the physical condition of the patient should be taken into consideration—whether or not she is anemic; and whether her surroundings are such as one could wish. The patient should be put into the hands of a person who is thoroughly competent and who will use the best judgment and not accede to the wishes of mother or child. A perfectly healthy child might menstruate at 12, another at 16, but if menstruation is delayed until 16 there are conditions there that should be looked into, conditions that may be a forerunner of something else.

1. **Acid-Fast Tubercle Bacillus.**—Maher maintains that the acid-fast tubercle bacillus is simply a most highly specialized acid-fast bacillus that has acquired the faculty of resisting the lytic power of the animal cell. And that like all other acid-fast bacilli, it was derived originally from a non-acid-fast bacillus. The hope of the infected animal lies in depriving him of his acid-fast armor and weapons. The great sensitiveness of the tubercle bacillus to change of environment *in vitro*, affords a key to the solution of Nature's cures of tuberculous animals. When the infected animal is cured by change and fresh air, is it not, Maher asks, because in the new environment the tubercle bacillus has difficulty in perfecting its acid-fast development and therefore grows non-acid-fast or poorly acid-fast, or breaks up into cocci, which may or may not win the next battle with the cells? If the cells win, the patient recovers. If the cells lose, the coccal and rod forms quickly break-down surrounding tissue entrenchments. The so-called secondary invaders are practically always, he says, derivatives of the struggling acid-fast tubercle bacillus. The acid-fast tubercle bacilli develop into culturable cocci and non-acid-fast bacilli.

4. **Eye-Strain.**—Richards mentions disorders of sleep, posterior nasal catarrh, digestive disturbances, and claims to have given relief in asthma and hoarseness by fitting glasses.

22 Conical Stump After Amputation in Childhood. C. A. Powers, Denver, Colo.

18. **Etiology of Elephantiasis.**—Shattuck undertook by a review of the literature to ascertain the present state of knowledge of this disease. He now believes that the essential characteristics of typical acquired elephantiasis are lymphangiectasis, hyperplasia of connective tissue, and chronic edema. The relation of these to each other in the production of elephantiasis is not clear. It appears that these changes may frequently be attributed to the interaction of stasis and of inflammation. Stasis always occurs early and persists. Inflammation may precede or follow stasis, or may not be manifest at any stage of the disease. Inflammation when present may be acute or chronic; and is generally traceable to bacterial infection. Either chronic stasis or inflammation from any cause may predispose to elephantiasis, but even when they occur together, elephantiasis does not always result. There is reason to suppose that congenital weakness or anomalies of lymphatics may play an essential part in the production of some cases of elephantiasis; and that such weakness or anomalies can be inherited. The filaria is an important factor in the production of endemic elephantiasis of some regions, but it is not essential to the occurrence of endemic elephantiasis. Elephantiasis in filarial regions results indirectly from filariasis through bacterial infecton. Sporadic lymphatic elephantiasis and endemic elephantiasis are not essentially different.

20. **Technic in Arthrotomy.**—In this series of 198 cases there were thirteen erasions—nine in men, four in women. There was one slight skin infection among these. One case was so bad when the joint was opened that an excision was attempted, but the disease extended so far into the tibia that a thigh amputation had to be done. One case was a wrist. The others were all tuberculous knee-joints. There was one death among this group, and that was a few days after leaving the hospital and was due to tuberculous meningitis. It was observed in studying the cases in this group, viz., the excisions and erasions, that the danger of disseminating a tuberculous infection through surgical procedure is not a wholly negligible matter. The authors show that care must be exercised to allow Nature to start her protective immunizing processes, both local and general, before one takes the risk of opening up new tissue to infection and absorption.

21. **Cutaneous Diphtheria.**—In the case reported by Place, that of an infant aged 7 months, two days before admission swelling and redness became marked over the area of the abdomen, genitals and thighs covered by the diaper. There was a considerable thin discharge. Over the lower third of the abdomen, the vulva, perineum, anterior part of buttocks and the upper quarter of the internal surface of the thighs, the skin was markedly reddened, swollen and covered with a grayish hyaline membrane, firmly adherent, and when forcibly removed left a granular area which bled easily. Scattered through this area, especially the lower part, were small various shaped islands of healthy skin, some connected by narrow bands of healthy skin. There were no vesicles or pustules, and the skin elsewhere was normal. Cultures from the skin showed typical diphtheria bacilli. Cultures from the nose and throat and from the nose and throat of the mother showed no diphtheria bacilli. The necropsy showed, besides the skin lesions, some hyperplasia of the lymphoid tissue, "septic" spleen, beginning bronchopneumonia of both bases and some pus in the middle ear. The source of the infection not discovered.

38 Significance of Cough in Disease. J. B. Hardy, Stanton, Neb.

37. **Prolapse of the Uterus.**—The essential factor in the production of prolapse of the uterus, says Roeder, is the recession of the cervix from the hollow of the sacrum. In the posterior positions of the uterus in nullipara we often find the posterior vaginal wall shorter than normal, and it is just here where the primary cause of the trouble lies. Simple shortening of ligaments or suspensions is not so successful, because the cervix is held more firmly out of place by the patient's abnormally shortened posterior vaginal wall. In these cases Roeder first lengthens the posterior vaginal wall, through the vagina, by a transverse incision, freely loosening it from the rectum, and sewing the transverse incision up longitudinally, then proceeding with the abdominal operation. In case the incision through the vagina seems too difficult, he opens the abdomen at once, incises the peritoneum covering the cul-de-sac of Douglas, brushes back with gauze the posterior vaginal wall from the rectum, and sews the uterosacral ligaments to the loosened vaginal wall, covering all denuded areas with peritoneum. Then, after the method of Coffey, he folds the inferior half of the broad ligaments over the posterior portion of the uterus, the superior half over the anterior, which helps to antevert the uterus. The round ligaments are shortened and strengthened at the weakest points after the method of Mayo, folding them over at the attachments of the internal ring.

39. **Dislocation of Atlas.**—While riding, the patient's horse stumbled and fell, throwing him over its head in such a way that he struck with the principal weight on his forehead. He felt something "snap" in his neck and had to support his head with his hands if he made a sudden movement, and for this reason he could not get back on his horse, but was able to walk home several miles, although he had con-

siderable pain in the occipital region. He could not turn his head from side to side and could not open his mouth more than half an inch. He found that swallowing was interfered with by something which pushed forward the front part of his neck. For three weeks he went about visiting among the neighbors, waiting for conditions to improve so that he could return to work. He could walk with tolerable comfort. When there was any unusual action or strain or when he wished to get up from bed or from a reclining posture, he had to support his head with his hands, but when erect he could walk long distances without distress. He reported that he frequently walked as far as 10 miles a day, but could not ride horseback or in a wagon or buggy. The pain in the occipital region continued, he tired more easily than before the injury and the stiffness and swelling did not disappear. After waiting three weeks a diagnosis of dislocation or fracture of a cervical vertebra was made. There was absence of motor, sensory or reflex symptoms. He complained of pain on moving the head and at times complained of frontal headache. A curious symptom was that pressing his feet against the foot-board of his bed seemed to relieve the headache temporarily. He complained of pain in the muscles of the neck, all of which were held rigid and tense and sometimes there was twitching of the muscles of the right side of the face. At times he had a pain which began at the level of the thyroid crest which pressed forward and extended around to the left ear. The face was held slightly to the left and could be rotated a little to that side, but not at all to the right, while the head was slightly tilted to the right. This tilting of the head was greater than it appeared as the bending of the lower vertebræ compensated the deformity at the junction of the atlas and axis. He entered the hospital in the evening and was put to bed. Appetite was good; bowels were constipated; pulse was 88; respiration was 16; temperature was 98.6. The first night he slept quietly and comfortably from 8:30 p. m. to 6 a. m. After making a careful examination, a diagnosis of dislocation of the atlas with probable fracture was ventured. The skiagraph fully confirmed this diagnosis. This was taken with the patient lying on his left side and showed the forward dislocation of the atlas and gives a reasonable presumption of fracture of the odontoid. It would hardly be possible to get such a picture with the odontoid intact. A plaster splint was made to fit the back, shoulders, neck and back of head, which was held in place by bandages. This kept him rigidly in one position and made him more comfortable. After three weeks an attempt was made to reduce the dislocation, first by manipulation, extension, flexion, rotation, without success, and then by the open method. A median incision was made extending well up on the occiput and down to the spinous process of the sixth cervical vertebra. This gave a free exposure of the region of the atlas and axis. The spinous process of the axis had been fractured near the tip and the lamina on the right side of the axis had been fractured. Both of these fractures were firmly united in the seven weeks which had intervened. The right lateral process of the atlas was rotated forward into the intervertebral notch. The posterior arch of the atlas was thrown upward almost against the edge of the foramen magnum and forward across the opening. After securing free exposure of all parts, an attempt was made to effect a reduction, but without avail. A new plaster cast was applied to the head, neck, shoulders, and back and the patient returned to bed in good condition. He was kept in the cast for six weeks, at which time he was able to walk about comfortably, but he did not leave the hospital until December 12. He seemed perfectly strong and well, except for a stiff and deformed neck. About five weeks later he returned with symptoms indicating that degeneration of the cord was in progress. The patient died from respiratory failure.

50. Abstracted in The Journal, July 16, 1910, p. 1246.

51. **Two Interesting Liver Cases.**—Both cases reported by Mitchell were in young subjects. Both began insidiously with all evidences of a simple catarrhal jaundice and were so looked on until considerable and rapidly increasing enlargement of the liver showed that they were of more serious nature. In both jaundice was very marked. In both the liver shrank rapidly in size as the symptoms of grave icterus developed. In one patient this condition developed abruptly and terminated in death in the surprisingly short time of thirty-six hours. In the other patient the development was somewhat less abrupt and the duration several days. In both the terminal clinical pictures most clearly resembled acute yellow atrophy. The pathologist showed that both these cases were instances of cirrhosis of the liver.

52. Abstracted in The Journal, June 4, 1910, p. 1895.

53. **Syphilitic Ulceration.**—In Ravogli's case, the ulcer on a thick and infiltrated base consisting of red elevated nodules, began in the upper part of the right inguinal region, involving the whole fossa cruro genitalis and the labium of the same side. In an irregular serpiginous way it descended down to the thigh involving a large area of the gluteal region and the perineum, descending toward the anus. One ulcer was also found on the other side of the gluteal region just on the surface of the skin touching the ulcerated spot of the opposite side showing a local inoculation. An extensive scar on the posterior region of the thigh bears witness of more extensive ulceration already healed up. The ulcer consisted of an aggregation of small nodules causing an infiltration of the whole surface. Some of the nodules were broken down, some covered with thick crusts, some vegetating forming thick papillæ. The right labium was thickly infiltrated, enlarged, elephantiasic, and through the ulcerated surface, adherent to the thigh and drawn downward. The diagnosis was that of syphilis ulcerosa præcox. Wassermann test with Noguchi method gave a positive reaction. The Moro test for tuberculosis was negative. The woman was treated generally with gray oil injections twice a week, and internally potassium iodid and an iron tonic. In a short time she improved considerably in her nutrition and in her general health. The ulcer was treated locally by bathing with 1 to 2,000 bichlorid solution, and covered with calomel in Wilson ointment, 20 grains to the ounce. The ulcer was slowly improving, yet not fast enough to give satisfaction. The patient was subjected to general anesthesia with ethylchlorid followed by ether. The ulcer was thoroughly curetted, the labium was detached and corrected; during the operation it bled profusely. The hemorrhage was checked, the wound was covered with iodoform dressing. The same manner of dressing was continued, the wound was clean, and in a relatively short time, healed up completely leaving a soft regular scar.

Yale Medical Journal, New Haven

October

57 A Medical Retrospect. W. T. Councilman, Cambridge, Mass.
58 *Therapeutic Use of Tuberculin. D. R. Lyman, Wallingford, Conn.

58. **Therapeutic Use of Tuberculin.**—Statistics for sixty-seven cases treated with tuberculin at the Gaylord Farm Sanatorium, and 374 without, in the five years prior to Jan. 1, 1910, show that of the incipients, 82 per cent. of those treated and 83 per cent. of the untreated are now at work with the disease arrested. Of the moderately advanced, the figures are 40 per cent. for the treated, and 48 per cent. for the untreated; of the far advanced, 10 per cent. and 11 per cent. respectively. These figures show no appreciable difference between the treated and untreated cases; the slight additional percentage being, in fact, in favor of the untreated. If, however, says Lyman, one reviews these same cases from

the standpoint of any possible increase in resistance, as shown from the death-rate, it is found that of the incipients treated with tuberculin none has died, while there are 4 per cent. of deaths among the patients untreated; the moderately advanced show 27 per cent. as against 19 per cent., indicating, perhaps, some increase in resistance from its use, especially in the more advanced cases. Lyman's impressions on the whole are more hopeful as to its future in tuberculosis therapy than these statistics would imply. It is not in itself a cure, but in suitable cases, and given with utmost care, it is undoubtedly a great aid in some instances. In many cases after the ordinary sanatorium régime has brought the patient's general condition up to normal, but when constant relapses are occurring and the patient is apparently losing ground, its use has been followed by marked and often apparently permanent improvement. The patients experience a distinct increase in general strength, they can do more without tiring, and sometimes there is distinct increase of appetite, decrease of slight persisting temperature, and relief of pain from chronic dry pleurisy.

62. An abstract of this paper appears in Society Proceedings, this issue.

63. **Carcinoma of Fundus of Bladder.**—Hagner claims that it is possible, with exercise of proper care, to remove tumors from the fundus and lateral walls of the bladder without the slightest traumatism to the tumor mass by his method. The operation is impracticable for tumors of the bladder base. The following is a description of the operation as employed in one case: The bladder was irrigated, and on account of bleeding, adrenalin 1:10,000 was instilled and allowed to remain five minutes. The bladder was then distended with 350 c.c. of salt solution, and a Nitze cystoscope was introduced. This was held in place by an assistant, while a suprapubic incision down to the bladder wall was made. The prevesical fat was well separated and the tissues well retracted by wide lateral retractors so as to give a good exposure of the bladder wall. The growth was then inspected through the cystoscope, the right hand holding the cystoscope; with the left, a needle was pressed on the fundus of the bladder, and the dimpling caused thereby was readily seen through the cystoscope. The needle was carried first to the left of the growth at a sufficient distance to give a margin of healthy bladder wall, it was then plunged into the bladder, being held in place by an assistant. The same procedure was carried out at the right of the growth and at the lower border. An attempt to place a needle above would have penetrated the parietal peritoneum, as this was involved in the growth. A sharp knife was then carried to the outer side of the three needles placed around the growth, the portion of the bladder wall to be removed being clamped at its cut edge as soon as the incision was started. The bladder wall containing the growth was lifted up by the clamp and held by an assistant. The fluid left in the bladder was removed by a large syringe through the suprapubic wound to prevent its entrance into the peritoneal cavity. The incision in the bladder wall was then carried upward into the peritoneal cavity and a portion of parietal peritoneum covering the growth was removed. The bladder and peritoneal wounds were then closed by two rows of sutures, a suprapubic drain being left in the bladder.

64. **Intraperitoneal Cystotomy.**—Tennant advocates transperitoneal cystotomy in selected cases. He says that more successful results in bladder work may be accomplished, with considerably less mortality and much greater comfort to the patient, by the intraperitoneal route. In two cases, he found that it was possible to perform an intraperitoneal cystotomy in the presence of very marked cystitis. Both patients had a cloudy alkaline urine, with pus, colon bacillus and other pyogenic micro-organisms, but after careful consideration, it seemed best to use the transperitoneal route. Both patients were operated on, the bladder immediately closed, and successful results secured, sparing the patients annoyance and apprehension of a urinary fistula.

66. **Sac of Femoral Hernia.**—Murray holds that clinical experience, operative experience, and also evidence obtained from necropsies and from the pathologic laboratory are strongly in favor of the view that the sac of a femoral hernia is of congenital origin and is not acquired.

67. **Silver Wire in Cure of Hernia.**—Wiener regards chromic catgut as an unreliable suture material, but Pagenstecher linen, he thinks, is an excellent suture material. Silver wire, in some form, is a suitable suture material in many recurrent cases; and at primary operations when the tissues are poorly *developed. Immediate recurrence, in uninfected cases, in his* opinion, is usually due to chromic gut. There will be fewer recurrences, he declares, if surgeons entirely discard chromic gut sutures.

68. **Pneumatic Tourniquet.**—Bunts has devised an apparatus which is made of rubber and linen and consists virtually of two long rubber bags fastened together along their inner margins, but connected at the middle by an opening through this fastening which permits the air to circulate simultaneously in both tubes when inflated. If it be made of a single rubber bag, the inflation will cause the superimposed turns of the tourniquet to roll off of each other and thus relieve the constriction. With the double tubes this cannot occur, and the tourniquet remains exactly where placed. It is made of much the same material as the familiar obstetrical pad, which is sufficiently elastic, very strong and durable and can be readily sterilized. It has a tapering end which, after the tourniquet is in place, is tucked under the inflatable part and becomes fixed as soon as pressure is applied. From the middle of one of the bags projects a rubber tube with an offshoot and two stop-cocks, which permit, respectively, inflation by means of an attached bulb, and gradual diminution or total abolition of pressure by opening and allowing the escape of the air. If done slowly, undoubtedly venous engorgement would take place, but the inflature may be rapidly accomplished by a few pressures on the bulb, and if still greater precaution against congestion is needed, the limb may be elevated or a Martin badge applied before compressing with the tourniquet. It can be applied uninflated to the limb prior to its preparation for operation and then, when needed, the circulation can be shut off by compression of the bulb without any disarrangement of the preparations about the field of operation. If, for any reason during the operation, it is desired to restore the circulation or to see whether the vessels have been secured, the air may be slowly allowed to escape by the anesthetist or nurse by opening the stop-cock, and controlled instantly by the reinflation of the tourniquet, without having to readjust it.

85 **Lateral Curvature of the Spine.**—For several years Keppler has been using in these cases a simple apparatus which he constructed It works on the basis of leverage with the patient lying face downward on a mattress To a vertical bar two long arms are attached by means of sliding joints; and fastened to these are two smaller bars with the corrective pads At the free end of each arm is a hook on which the weight hangs The patient lies in front of the machine with the convexity of the spinal curvature immediately opposite the upright base, if the curvature is a double one the dorsal deviation is placed thus One arm is fastened very low on the upright, the pad being placed on the rib projection at the point of greatest deformity; thus the arm rises, the weight is high, pressure of the pad is down and outward. The other arm is fastened high on the upright, with the pad placed over the lower opposite deviation; it thus slants downward, the weight is low, the pad presses down and inward. The weights being attached—at first from 5 to 10 pounds each, later up to 25 pounds—the corrective act is exerted, and is continued from five to ten minutes. In single curvature only one pad is used; in round shoulders a smaller pad is placed between the scapulæ, while the shoulders are raised by means of a sand bag placed under the clavicles; and the apparatus can be used actively by placing the pad against the concave side, attaching a light weight and having the patient push up and outward against it intermittently. To be effective, Keppler says the active treatment must be given at least twice or three times a week. The daily use of a few simple general exercises and some suspension apparatus is also desirable. In fact, the home life of the patient must be well systematized, and the hours of school, rest, sleep and play regulated. The time of treatment varies; in simple cases good results may be obtained in about six months with occasional subsequent supervision; in severe and spastic cases no time limit can be set.

95. **Nephropexy.**—Courtney's method is, to some extent, a modification of the Edebohl operation. A transverse incision, from 1 to 1½ inches in length, is made at each pole of the kidney, well over the curvatures, and these are joined, in the form of a capital letter I, by a longitudinal median-line incision on the convex surface of the kidney. The outlined flaps of fibrous capsule are reflected well downward on the lateral surfaces of the kidney, where they remain undetached and are folded into a cord or ligament and so maintained by a whip-stitch of ten-day catgut. Four Pagenstecher linen or thirty-day catgut sutures are then placed at or near the four ends of the newly constructed cord or ligament. These sutures are inserted through the fibrous capsule, behind the ligament, over which a turn of each suture is made at a distance of about half an inch from the point of first insertion. The two ends of each suture are grasped separately by catch-forceps. The kidney is then partly returned within the wound, and the incised edge of the fatty capsule is brought forward and sutured to the fibrous capsule, below the newly constructed ligament, with fourteen-day catgut. The sutures may be interrupted at intervals of about three-fourths of an inch, and should surround the circumference of the opening in the fatty capsule The kidney is then completely replaced within the body, and, by means of needles, the two upper linen sutures, previously placed behind and around the ligament, are passed through the muscular and fascial planes only, of the abdominal wall, external to the incision and as near the twelfth rib as may be conveniently possible. The ends of each of these two sutures are again grasped in catch-forceps until the two like sutures below have been similarly placed, when all are tied sufficiently snug to raise and maintain the denuded surface of the kidney in close apposition with the raw surface of the quadratus lumborum muscle. The wound, or incision, is closed in the usual tier-suture manner and without drainage.

97 **Varicose Ulcers.**—The principle of Moore's treatment is mild medication, combined with continuous pressure by means of properly adjusted strips of adhesive plaster. With the average ulcer, all the preparation necessary is a thorough washing with soap and water before applying the plaster. A painful or so-called irritable ulcer should be swabbed very thoroughly with 95 per cent. phenol, repeated several times at intervals of three or four days, before applying the adhesive strips The phenol should be followed in about two minutes by alcohol, after which a gauze dressing should be applied. This treatment will relieve the pain and sensitiveness in a very few days, so that the pressure can be applied without causing pain When there is eczema about the ulcer this should be healed by the usual methods before applying the adhesive plaster. In case of annular ulcer, involving the whole circumference of the limb, the only successful treatment is amputation. After washing and shaving the leg it should be held horizontal by placing the heel on the seat of one chair while the patient is seated on another. The ulcer is then covered with dry calomel so that the cavity is filled level with the skin Beginning at a point about 2 inches below the ulcer, strips of adhesive plaster from an inch to an inch and a half in width should be applied around the limb, so that the strip above overlaps the strip below about a quarter of an inch, like the shingles on a roof. A sufficient number of strips should be applied so that the upper one extends 2 inches above the upper edge of the ulcer. They should be applied firmly, and flat against the leg, so that one edge does not press into the flesh. They should not completely encircle the leg, but should leave a strip of uncovered skin along the back about an inch wide. A roller-bandage should then be applied from the base of the toes to the knee. At first it is necessary to change the dressing every day, for the discharge from the ulcer mixes with the calomel, forming a thick paste which oozes out between the adhesive strips, and unless changed this often irritates the skin, loosens the straps and acquires an offensive odor. In a short time, however, the amount of discharge diminishes, and the strips can be left on for two or three days, the length of time being regulated by the amount of discharge. In a very few days the granulations begin to assume a healthy color, and a blue line of new skin appears around the edge of the ulcer. The progress is usually most gratifying, and after the discharge has diminished so that

the dressing requires changing only every third day, the patient can see the improvement that has taken place between dressings.

114 **Ureterocystostomy.**—The chief feature of this operation is the deliberate opening of the bladder, for the purpose of affording working space in carrying out the anastomosis With a liberal median incision the pelvic cavity is thoroughly exposed The ureter is liberated down to a point as near as possible to the base of the bladder. It is there cut off, leaving a free length of about 1½ inches The bladder is opened by a median longitudinal incision, about 2 inches in length This gives free access to the whole of the interior, with plenty of working space A point is selected on the surface of the bladder, which the free end of the ureter will easily reach If there be any difficulty in making the ureter reach the bladder, the latter may be dissected away from the pubes sufficiently to allow approximation The bladder is punctured at the selected point, and the ureter drawn through. When the broad ligament is present, the puncture is made to pass through this structure at a convenient point The end of the ureter is split, so as to make an upper and a lower flap, each about 1 centimeter in length The mucosa of the bladder where these flaps are to be united, is slightly denuded, and then each flap is sewed to the bladder wall by fine chromicized catgut The operation is completed by closing the bladder and covering the remainder of the ureter as completely as possible with peritoneum In the after treatment the bladder is kept empty by catheterizing every two or three hours for several days A permanent catheter should not be used, as it is almost sure to produce cystitis

115. **Statistical Study of Uncinariasis**—According to Chamberlain, uncinariasis is found among the Filipinos in probably not over 15 per cent of the general population, and is mild in type and of small economic importance The percentage of infection is higher in adult males, reaching 50 or 60 per cent among the Philipino scouts and Bilibid prisoners. From 65 to 85 per cent of the southern bred white recruits for the United States Army are infected with uncinaria, usually mildly, and these infected soldiers have been coming in considerable numbers to the Philippines, thus importing *Uncinaria americana* The majority of these soldiers, if not reinfected, become free of the worms by natural processes in about five years Uncinariasis, sufficiently marked to be evident clinically, is very rare among American men in the Philippines Even a routine stool examination among Americans showed few cases, seventy one out of 8,000 examinations at the Division Hospital and nineteen out of 800 examinations at the Fort William McKinley Hospital An exhaustive stool examination among Americans in the Philippines, Chamberlain believes, would probably show a somewhat greater frequency. Of the ninety cases of uncinariasis found at the above hospitals, only eleven were admitted for uncinariasis Forty five were admitted for gastro intestinal troubles, dysentery, diarrhea and sprue being the most frequent causes In about thirty out of ninety cases (33 per cent) there is a probability that the infection originated in the United States and was imported into the Philippines In the remaining sixty cases it is probable that infection occurred in the Philippines, and there is reason to believe the parasites were usually introduced through the mouth with food or water Chamberlain says that uncinariasis is of sufficient importance among Americans in the Islands to make an occasional careful search for ova desirable

116 **Intestinal Parasites**—The result of the work done by Rissler and Gomez is in accord with that of other authors regarding the almost universal infection of the whole population of the Philippines with intestinal parasites The chief infections in the districts covered by this report are from *Ascaris* and *Trichuris*, and their distribution is rather uniform, although in Santa Isabel the percentage of infection with *Trichuris* fell very low The distribution of the hookworm varies, Santa Isabel showing the highest percentage ever recorded in the Islands Males were more affected than females The percentage of hookworm infection does not appear to be affected by the nature of the soil on which the people live The *distribution of Amœba shows still greater variation* In and around Manila the percentage of infection is higher, but in the Cagayan Valley it is rather low Infection with *Hymenolepis*, while not found in Cavite and Rizal Provinces, is rather frequent in the Cagayan Valley Children are mainly infected Tapeworms are also more frequent in Cagayan and Isabela than in Cavite and Rizal The parasite known as the worm of Cochin China diarrhea, or *Strongyloides intestinalis*, was not found in Cagayan and Isabela, whereas it was frequently encountered in Cavite and Rizal Monads were found rather uniformly distributed in the cases, but ciliates were not encountered in the Cagayan Valley

118 **Antimalarial Prophylactic Measures**—The value of efficient sanitary measures is well shown in Dunbar's report A board appointed for the purpose recommended (1) filling in of the swampy land on the range and further clearing of the ground so that there should be no shelter for the mosquito within at least 200 yards of the range, (2) the erection of thoroughly screened quarters for officers and men. These recommendations were carried out and the quarters completed by the date of the opening of the target season. The buildings are of light construction, elevated about 4 feet from the ground, well ventilated and completely screened During the first quarter of last year there were 105 admissions to the hospital ship, giving 2,214 sick days, and the station sick quarters were constantly kept filled, and this has been the yearly experience since the range was established During the elapsed part, over one half, of the first quarter of the year, there had been eight admissions to the hospital ship for malaria, giving 120 sick days, and there have been only fifty-three patients treated at the sick quarters The administration of from 4 to 8 grains of quinin daily has been found

necessary. The treatment is, as a rule, continued for three weeks, but not necessarily or usually in the larger doses.

125 **Mali-Mali in the Philippines.**—Musgrave and Sison point out that the peculiar mimic psychosis in the Philippines known by the local name mali-mali is closely related to, but distinct from, the tics. Such somewhat doubtful tics as Giles de la Tourette's disease, jumping tic of Beard, myriachit of Hammond, and the salutatory tics in general, have much in common with the Philippine affection, but in all of these, with the possible exception of latah, there are indications of autospasm which is lacking in the local disease. Ramanemana, the dancing mania of Ramisiary, St. John's and St. Guy's dance, and perhaps other allied conditions, are more nearly hysterical manifestations; and while they have much in common with mali mali, they all show evidence of autostimulation, and when once established are capable of prolongation without any outside influence. The authors believe that mali-mali is probably an expression of mental degeneracy similar to that generally accepted for other conditions of the same group. However, its clinical manifestations do not clinically agree with those given for any other similar disease, and for this reason it is classified by them, tentatively at least, as a clinical entity.

1. **Diaphragmatic Hernia.**—Hernias through the diaphragm, Keith says, fall into two groups, the congenital and the acquired, the former being to the latter in the present series of thirty four cases as 26:8. The congenital hernias are chiefly those which occur at the unclosed pleuro-peritoneal passages (twenty one cases), the others being formed (five cases) by developmental extrusions of the abdominal viscera, chiefly liver, through the septum transversum. In a certain proportion of congenital cases it appears possible to adopt surgical measures for the cure of the condition

2 **Typhoid Perforations.**—There were treated in the Montreal General Hospital from 1897 to May, 1910, 2,051 cases of typhoid During this period there occurred ninety-three cases of perforation. In this series, then, perforation occurred in 4.53 per cent of the cases. In addition, Armstrong operated on three patients with typhoid perforation in another hospital and on one patient in a private house; of these four patients, three recovered. There are then, ninety-seven perforations, of which seventy-eight were operated on, and twenty-four, or 30.76 per cent. recovered. During the year 1909, there were sixteen perforations; nine were operated on, and nine, or 56.25 per cent. of the patients recovered. The figures for the year 1909 and four months of 1910, or up to May last, are the best of all. During this period there were twenty-two perforations, nineteen of which were operated on, with nine, or 47.36 per cent., recoveries. In this series of twenty-two perforations two very promising cases were lost, apparently by delay in obtaining consent to operation after the perforation was diagnosed. The increased percentage of recoveries, according to Armstrong, is, in part, due to the character of the epidemic, but chiefly to earlier diagnosis and earlier closure of the opening. The earlier diagnosis has been due largely to the development of the idea among the resident hospital staff that it is a serious reflection on their skill and professional attainments to fail to recognize a typhoid perforation, no matter how slow and chronic may be its appearance The final step toward lessening the mortality rate in typhoid perforation is the recognition by every one that it is a serious and humiliating oversight to fail to recognize a perforation when it occurs. An analysis of the cases show that perforation is more common in the severe forms of typhoid Fifty of the perforations occurred in cases described as severe forms of typhoid. Fifty of the perforations occurred in cases described as severe, twenty in moderately severe cases, and one in a mild case. Six perforations occurred in ambulatory cases, and in one of these it seemed highly probable that perforation had occurred sixty hours before admission to the hospital. Strange to say, this man recovered. Of the ninety-seven patients in whom perforation occurred, only seventy-eight were submitted to operation. Nineteen patients were not operated on for various reasons, the chief being failure to obtain consent from the patient, parents or guardians, the desperate condition of the patient, and non-recognition of the lesion. Twenty-six cases of perforation were associated with hemorrhage. Among these are not included instances of small blood-stained stools but only those cases in which the quantity of blood lost amounted to several ounces. As a class they are unfavorable. Three of these patients, however, recovered. In six cases, or 7.7 per cent, more than one perforation was found at the time of operation. The perforations were generally not far removed from each other In

four cases a second operation was undertaken for second perforation; with one recovery. In two cases, recovery would have followed the second operation had not a third perforation occurred—in one case seven days after the second operation and in the other twenty-one days after the second operation. In one case two operations were performed. At the first operation one perforation was closed. At the second operation two perforations were closed. The child finally died, and at the necropsy the lower two feet of the ileum were necrotic, twelve perforations being counted.

It has been Armstrong's practice to close the opening in the simplest way, that is, by one or two sutures through all coats, and a row of Lembert sutures placed transversely at right angles to the long axis of the bowel. He then infolds in a similar manner with a row of Lembert sutures all the ulcers found to have a thin, suspicious, necrotic-looking base. Two alternatives have been carried out in a few cases. In two the suspicious portion of the gut was resected with end-to-end anastomosis. Both patients died. In two the suspicious looking gut was delivered, and cared for outside. The gut was wrapped in gauze, and allowed to rest on the abdominal wall. These two patients, after doing well for a time, eventually succumbed, one of them from pneumonia. Armstrong says that resection should probably be reserved for special cases in which the danger of further perforations over a considerable section of intestines seems imminent, and the patient's general condition warrants undertaking an operation that requires a little more time and a little more shock.

4. **Diet Before Operation.**—Collum is more liberal in this respect than is customary. Thus, supposing an operation (in a healthy subject) is to be performed at 9 o'clock in the morning, he says the patient should be left asleep, unless he awakes of his own accord, until at any rate 7:30, when he may be given his enema. Then, if he be accustomed to breakfast about 8 o'clock, he may have a thin slice of bread-and-butter, or a small piece of toast, with as much tea to drink as he desires. He will then be able to settle down much more contentedly to his newspaper until the surgeon arrives. If the operation be at 10 or 11 o'clock, he may have a similar breakfast, but with two thin slices of bread-and-butter, if he wishes, or a somewhat larger piece of toast, provided his usual breakfast hour be 8 o'clock. If, however, he be accustomed to breakfast at 9, the amount of solid food should be as in the first case, unless the excitement of the approaching ordeal has caused him to awake earlier than usual, under which circumstances he may also have his small meal a little earlier. If the operation be arranged for 12 or 1 o'clock, he may be given an ordinary light breakfast at the usual time; meat, however, being avoided. A glass of water might in this case, be taken with advantage about 11 o'clock. For an operation at 2 or 3 o'clock, the ordinary breakfast should be taken at the usual time, and a cup of hot clear soup or beef-tea at 1 o'clock, together with a little water to drink. This same arrangement is suitable for a patient to be operated on at 4 o'clock, except that in this instance a little toast, bread, or biscuit may be given with the soup. If 5 o'clock be the appointed hour, the breakfast and lunch should remain the same, but in addition a cup of tea may be taken at, or a little before, 4 o'clock. If the hour is 6 o'clock, the patient may have his ordinary breakfast, and then a light luncheon consisting of fish or poultry at about 1 o'clock, followed by tea with bread-and-butter at 4 o'clock. Finally, a patient who is to be operated on at 7 o'clock may partake of his usual breakfast, lunch and tea, simply avoiding currant cake or anything rich at tea-time. No fruit of any kind should ever be taken on the day of the operation.

22. **Excretion of Creatin in Diabetes Mellitus.**—In Taylor's present series of cases—sixteen in number—it was found that the output of total nitrogen in diabetes was not always greatly increased even with a comparatively high intake of protein; indeed, the nitrogen was frequently abnormally low. There seemed to be some connection between the carbohydrate metabolism and the creatin-creatinin metabolism. As regards creatinin, it was found that the output was not increased to any considerable extent even when the patient was on a highly nitrogenous diet. Creatin, on the other hand, a substance never found in the normal urine if the diet be free from creatin and creatinin, was always found. It was present even when the patient was kept on a creatin-creatinin free diet. Some further work was carried out in conjunction with Dr. E. P. Cathcart on the creatin excretion after the induction of glycosuria by means of injections of phloridzin. Here it was found that if the animal were allowed only a small quantity of carbohydrate in the diet creatin appeared in the urine during the time sugar was being excreted. It disappeared as soon as the sugar excretion ceased. On the other hand, if the animal were given very large amounts of carbohydrate, so that even during the period of glycosuria there was still an abundance of sugar in the body, then no excretion of creatin accompanied the output of sugar in the urine. It was further found that fats, even in very large amounts, could not replace the carbohydrate. A liberal supply of fat combined with an amount of carbohydrate, sufficient to prevent the appearance of creatin in the urine under normal conditions, did not check the excretion of creatin when glycosuria was induced.

26. **Phagocytosis of Erythrocytes by Endothelial Cells.**—Meek found that preparations of endothelial cells are especially suitable for observations on hemophagocytosis. Human blood serum, whether from "natural" or "immune" sources, which cause agglutination of other red-blood corpuscles, can be shown to also bring about phagocytosis of these erythrocytes by endothelial cells. The amount of "hemo-opsonin" in such sera is closely related to the amount of "hemagglutinin" which they contain.

30. **Ascites and Subcutaneous Drainage.**—Paterson employs a glass drain of such a shape that it will not slip into the peritoneal cavity. These drains or buttons are of various sizes, so that a suitable one can be chosen for each case. The buttons consist of a perforated glass cylinder expanded into a flange at each end. The largest size measures 1 inch across the flanges, and has a canal 1/12-inch wide. The flange itself has a thickness of about 1/16 inch. The diameter of the flanges and the width of the canal may be the same in the various sizes; but it is essential that the cylindrical part should vary in length, as this part has to pass through the thickness of the abdominal muscles, and as this thickness varies in different individuals so also must the length of this part of the button. Care must be taken to have all the edges and corners rounded and that every part is perfectly smooth. The operation is a simple one. An incision, about 3 inches long, is made in the middle line below the umbilicus, and the peritoneal cavity is opened in the line of the incision. If the abdomen has not been previously tapped the greater part of the ascitic fluid escapes at this stage. The omentum is then drawn down and removed at a level well above the point where the drain is to be placed, because, if left, it very soon passes into the opening in the drain and completely blocks it. The subcutaneous tissues are now dissected outward, on one side, till the semilunar line is exposed, and through this an opening is made into the peritoneal cavity. This opening should just be large enough to permit the button being placed in position. The drain may be passed either from the peritoneal or subcutaneous side. but if from the latter care must be taken to avoid stripping the peritoneum from the edge of the opening when inserting the tube, or the flange may come to lie between the peri-

toneum and the subperitoneal tissues. By slipping one flange edgeway through the opening there is no difficulty in placing the button in position. When a suitable size has been chosen one flange should lie flat on the peritoneum and one on the abdominal aponeurosis, without any pressure being exercised on the intervening tissues. If too long, the apparatus would project into the peritoneal cavity, and the intestines might get nipped between the flange and abdominal wall; while if too short, the button would tend to cut its way through the thickness of the tissues in its grasp. If the opening for the drain has been made too large and the edges do not grip the button firmly, a purse-string suture should be placed close to the button on the aponeurotic side, so that when tightened the soft tissues are brought into close contact with the groove in the drain. The subcutaneous tissues are next closely stitched by a continuous suture to the anterior layer of the sheath of the rectus. This suture is placed about 1 inch from the margin of the primary incision and parallel with it. By this means the superficial end of the drain is shut off in a compartment of its own, and the fluid, as it escapes from the peritoneal cavity, is prevented from throwing too much strain on the suture closing the skin incision. The primary wound is sutured in the usual manner, the skin being closely stitched by a buttonhole suture to prevent any leakage. A collodion dressing applied to the wound gives additional support. This dressing is reapplied as often as required till the skin wound is firmly healed. For one or two days afterward the patients usually complain of pain in the neighborhood of the button, but when this has passed off no further discomfort is experienced. If the quantity of peritoneal exudate be considerable, a fluctuant swelling, almost the size of the fist, forms within twenty-four hours in the subcutaneous tissues around the drain; but as absorption becomes established in the superficial vessels the swelling diminishes, till only a slight edema remains to show that fluid is still escaping. When the exudate is small in quantity the swelling does not pass beyond the state of edema. Paterson has performed this operation in several cases of ascites secondary to malignant disease, and also in cases of cirrhosis of the liver, with marked diminution of the abdominal distention, and to the great relief of the patients.

42. Pulse Preceding Epileptic Attack.—In the course of a research whose object was to determine in what way, if any, the action of the circulatory organs in epileptics differs from that in normal persons, the authors succeeded in obtaining satisfactory tracings immediately preceding and up to the fit in five epileptic major attacks. The tracings were taken with an Erlanger sphygmomanometer, using an external pressure that was usually below the minimum blood-pressure. The experiments consisted in taking long tracings at varying external pressures, together with a record of the respiration. The patient during the time lay comfortably on a bed. In all the records the respirations are markedly irregular; sometimes an occasional sighing respiration is seen, now and again a suspicion of Cheyne-Stokes respiration or slow tonic waves superimposed on the general respiratory undulations. In the opinion of the observers these variations bear no intimate relation to the fit, though they may be an expression of the conditions in the epileptic brain. They are seen in many epileptics quite apart from the fits or the "fitty" state, they vary much in the same patient from day to day, and they are often to be found in patients without epilepsy, especially in neurasthenics. In the first fit observed, the external pressure in the armlet was 78 mm. Toward the middle of the tracing was a deep respiration followed by a short character. The blood-pressure record is even except for the slight depression that occurs with the deep respiration. Immediately preceding the irregular movements of the lever which indicate the stage of tonic spasm, the upper and lower limits of the pulse oscillate somewhat, but there is no more than a slight lessening of the amplitude of pulsation, and even in the imperfect record of the pulsations when the tonic spasm has begun there are indications that cardiac action is uninterrupted. In the second case there was considerable irregularity in the respiratory tracing. The blood-pressure tracing, though taken at the external pressure of 100 mm., has a small amplitude; it shows well the respiratory undulation of pressure that some persons show more than others. In the second half of the tracings the amplitude lessens much and again increases toward the place where the irregularities which mark the onset of the fit begin. Pulse beats continue right up to the tonic spasm with regularity and only a trivial alteration in general level. The onset of the fit was gradual and allowed of a more detailed study. The records put forward in this paper are said to prove that there is no alteration of the pulse sufficiently definite to effect the amplitude of the wave up to the point when clonic convulsions prevent its being properly recorded, and in more than one record the fit has been noticed to be in progress before the record was interfered with. As regards the blood-pressure, the authors assert that in none of the records does such a lowering of general blood-pressure take place as to suggest that cerebral anemia from a general cause could have produced the convulsion, for in conditions in which lowered blood-pressure produces a general spasm, as for instance in Stokes-Adams disease, the convulsions occur after a time interval of several seconds after the pulse has stopped. In more than one of the tracings the patient was noticed to be in the fit and unconscious while little recognizable change was evident in the pulse or blood-pressure.

43. Influenzal Septicemia.—The two cases of influenzal septicemia which Thursfield records, will, he says, when considered in the light of recent work on so-called influenzal meningitis, lead inevitably to the conclusion that what has been hitherto regarded as a specific organism is, in reality, only one of a group, the members of which have similar, if not identical, morphologic and cultural characteristics, but different pathogenic properties. In certain cases of endocarditis and septicemia, an organism identical in all respects with *B. influenza* can be isolated from the blood, and is in all probability the cause of the illness. Furthermore, organisms identical in all respects with *B. influenzæ* are found in a number of patients who die of the acute specific fevers, especially in the bronchopneumonic areas. Thursfield also believes that Bordet's bacillus, an organism identical in shape and size with *B. influenzæ*, but capable of differentiation in culture, is the probable cause of pertussis, and that a bacillus identical with *B. influenzæ*, both in morphologic and cultural characteristics, but capable of differentiation by a study of its pathogenic effects on animals, is the cause of a septicemic form of cerebrospinal meningitis. Again, an organism identical in all respects, morphologic, cultural, and pathogenic, with *B. influenza* is a cause, he thinks, of suppuration in the middle ear and in the sinuses of the nose.

44. Hereditary Hemophilia.—Twelve patients were examined by Addis. They were descended from six different hemophilic stocks in Scotland, England and Germany. In none of these families was there any known instance of a departure from the characteristic type of transmission, i. e., through the females to the males. His results showed conclusively that there is a delay in the coagulation of hemophilic blood, a delay which in some cases is very pronounced and which far exceeds any retardation of coagulation observed in other diseases. Clinically, the cases fall into three groups. The first is that in which the patients were scarcely ever free, for any length of time, from some sign or other of the disease, even in the absence of any traumatic accident greater than those inseparable from ordinary life. The second group is that in which trivial accidents did not lead to observable hemorrhage. In the third group a still greater degree of injury was required to lead to any appreciable amount of hemorrhage. The only practical difference between the patients of this group and ordinary individuals was that on the occurrence of such a wound or injury as would always produce an appreciable amount of bleeding in any one, the bleeding in them persisted for a longer time. The degree of the defect in coagulation corresponded with the degree of the severity of the clinical symptoms. The coagulation of blood flowing from a wound Addis says is induced by thrombokinase added to it from the tissues, and the rapidity of coagulation varies directly with the amount of this thrombokinase. Much larger quantities of thrombokinase are required to produce rapid clotting in hemophilic than in normal blood. In a wound in a hemophilic, coagulation may therefore only occur in those parts where the concentration of thrombokinase is highest, i. e., on the sides of the wound. But this clot prevents the addition of further quantities of thrombokinase from the tissues, and when the amount of thrombin liberated from the primary clot is insufficient to lead to the complete coagulation of the blood in the center of the wound, bleeding may continue indefinitely. Hemorrhage Addis claims is no more easily induced in a hemophilic than in a normal person. The distinction is not in the occurrence but in the amount of bleeding.

46. **Endocarditis.**—Microscopic examination of the *a. v.* node and bundle in two cases of acute endocarditis revealed well-marked inflammatory lesions in the parts. In one case, in which the *a c* interval in the jugular curve was prolonged, the lesions implicated the bundle; in the other, where the *a c* interval was very short, the node alone was affected.

47. **Tuberous Sclerosis.**—The essential points in the case reported by Fowler and Dickson are: A female infant developed in an apparently normal fashion for a year, then had "fits" lasting for several hours, thereafter remained in a semiconscious condition for four weeks, dying of an intercurrent empyema. During the whole of her stay in the hospital her appearance suggested cerebral mischief, but having departed from the diagnosis of meningitis the authors did not know what was the matter. The lumbar fluid was perfectly clear when first withdrawn, but, as it cooled, became opalescent from a precipitation in it of minute shreds of fibrin about 0.5 mm. long. It was equally unlike the coagulum which often forms in the cerebrospinal fluid from a case of tuberculous meningitis, and the turbidity produced by pus. The brain was found to be slightly increased in size, and scattered over the surface of the cerebrum there were numerous nodules, varying from about the size of a pea to that of a small walnut, about a dozen or more being embedded in the surface of each hemisphere. These nodules were extremely firm, and their position could be determined most easily by running the fingers over the surface, the sudden transition from ordinary soft brain tissue to dense resistant nodules of almost stony hardness being very striking. In color they were pearly white. The pia arachnoid which was thin and comparatively non vascular, was not adherent over them, stripping easily from their surface. The general contour of the convolutions was not disturbed by their presence, the affected convolutions were slightly thicker or broader than normal, and projected to a very slight but appreciable degree above the general level of the cerebral surface. Some of the nodules showed a moderate degree of umbilication, and other irregularities which gave them a finely nodulated or granular appearance, while others again, presented a perfectly smooth surface. On section the nodules were situated mostly in the grey matter, but the larger of them also projected well into the subjacent white matter, which they closely resembled in color. These appearances suggested that the condition was a replacement or diffuse infiltration of the affected areas by some sclerotic process, rather than anything of the nature of syphilitic gummata or tuberculous nodules. No nodules were found in the cerebellum, pons, medulla, or spinal cord, all of which to the naked eye at all events, appeared normal. On making sections of the brain, numerous small nodules, about the size of hemp seeds were found projecting into the lateral ventricles. These were hard and firm like the larger cortical nodules, and were not connected with the choroids.

48. **Coupled Rhythms of the Heart.**—In all the cases of this series presenting a coupled rhythm there have been signs of mitral regurgitation or evidence of cardiac failure. The authors have never observed a coupled rhythm in an individual who did not manifest some evidence of cardiac weakness. The cases in which the coupled rhythm was long maintained were cases of pronounced heart failure, but in others, presenting a coupled rhythm for shorter periods, the degree of heart failure was almost as severe. With the exception of one case in which the ventricular rate was 92.3 per minute, and cases of auriculo-ventricular heart block, the ventricular rate was of moderate frequency. Some of the patients were taking digitalis, others were not. It is claimed that coupled rhythms of the heart may occur from various causes. They are often due to a regularly recurring extrasystole, which is most frequently of ventricular origin. Synchronous contraction of auricle and ventricle and an undue prolongation of diastole necessarily produce an increase of the intracardiac pressures, and are often followed by a premature systole. It is suggested that, whenever an enfeebled heart is unduly irritable in an abnormal site, any excessive rise of intracardiac pressure may induce a regularly recurring premature systole which originates in the irritable area. The coupled rhythm so often noticed in cases of "perpetual arrhythmia" under the influence of substances of the digitalis series, is probably produced by a mechanism similar to that of the coupled rhythm in which an extrasystole recurs after each physiologic beat.

57 *Action of Alkaline Saline Mineral Waters on the Gastric Secretion. A. Theohari and A. Babes.
58 *Hemorrhagic Infarct of the Mesentery and Intestine in Typhoid Fever. E. Chabrol.

57. **Action of Mineral Waters on the Gastric Secretion.**—This article reports the results of experimental research on dogs with a Pawlow fistula. The gastric secretion is notably influenced by different mineral waters, the various elements being influenced in different ways. The water of one of the springs tested contained 9.7 gm. of sodium chlorid and 9.7 gm. of sodium bicarbonate and this water invariably checked the gastric secretion. Water from another spring with 13.2 gm. of the chlorid and only 6.9 gm. of the bicarbonate stimulated the secretion, increasing it by 107 per cent. in some of the tests. The average increase was from 40 to 83 per cent. The free hydrochloric acid increased from 26 to 38 per cent. but the proportion of pepsin was reduced.

58. **Typhoid Infarct in the Mesentery and Intestine.**—Chabrol gives an illustrated description of the findings in the case reported and the clinical picture presented. Should the condition demand immediate operation, examination of the blood,

showing the absence of leukocytosis and hyperfibrinosis, will exclude peritonitis from perforation. Melena is common in both infarct and intestinal hemorrhage. He reviews the literature on the subject, saying that the lesion is generally in the small intestine, especially the jejunum, and that there may be superposed infection.

59 *Erysipelas and Peritonitis M Vallas
60 *Temporary Tracheotomy for Foreign Bodies in the Trachea or Bronchi Collet
61 Suppurative Thyroiditis During Whooping-Cough Collet

59 **Erysipelas and Peritonitis.**—Vallas' first patient was a healthy girl of 16, tending a woman with a severe erysipelas of the face The young girl was suddenly taken with serious peritonitis, succumbing on the fifth day. Necropsy revealed an acute streptococcus seropurulent peritonitis but no sign of perforation; the genital organs were normal. In another case a woman of 45 developed symptoms suggesting acute peritonitis but the cecum and appendix were healthy and the focus was found in the peritoneum and the lower part of the ileum. Four days after the mother's laparotomy in the hospital, her child at home, 4 years old, developed erysipelas of the face In Bonnet's case, an infant died with acute purulent peritonitis but all the abdominal viscera were found healthy The second day after the child's death, the mother developed erysipelas of the face. These cases indicate that erysipelas may be contagious during the prodromal stage and that it may induce an isolated peritonitis, and that both the erysipelas and the peritonitis may have been drawn from the same source

60 **Temporary Tracheotomy for Foreign Bodies in the Respiratory Tract.**—Collet advises a simple technic which he has found very useful. As soon as the trachea has been opened and the cannula introduced, he sutures on each side the lips of the wound in the trachea to the lips of the skin wound. This provides a large opening which can be made to gape still wider by traction on the threads. It provides an ample outlet for the foreign body, while it permits thorough inspection of the lower part of the trachea. In one case a cherry stone was coughed up several hours after this opening had been made; the cannula had been introduced and removed a number of times in the interim In the case of one infant the head was lowered and the foreign body, a piece of bone, was readily removed. No special instruments are required as the bifurcation can be readily inspected as soon as the cannula is withdrawn. Collet's experience shows further the remarkable ease with which a foreign body moves around from one side to the other; bronchoscopy may show it *on the right side* at one time and on the left at the next. Another advantage of this technic is that it permits ample intake of air, even without the cannula; it might be found useful also, he thinks, in membranous croup.

October 29, No 87, pp 809-816

65 Metastasis in the Dorsolumbar Vertebræ of Latent Cancer in the Thyroid A Mignon and G Bellot.

64. **The Lung in Heart Disease in Children**—Hutinel comments on the difference between signs in the lungs and pleura in heart disease in children and in adults. There seems to be a closer connection in children between the pericardium and the pleura, he states, so that a process in either is liable to involve the other more readily. The coexistence of double pleurisy with endocarditis and pericarditis, for example, is so characteristic that it sometimes is a clue to the rheumatic nature of the heart trouble when tuberculosis might otherwise be suspected In one such case a youth of 16 grew pale and emaciated and finally was forced to keep to his bed. There was a history of tuberculous peritonitis in early childhood from which he had apparently entirely recovered. The discovery of right pleurisy led the physician to diagnose tuberculosis as the cause of the boy's illness, but Hutinel, who was called in consultation, found the pleurisy bilateral, a systolic murmur at the apex and other signs indicating cardiac involvement; inquiry brought out that there were certain vague pains in the knees. On these bases he excluded tuberculosis and the complete recovery, except for a slight heart trouble, has confirmed his conclusion. Extension of a pleural process to the pericardium is also common; the pleura and lungs should be closely supervised in all cases of heart affections in the young and the heart region explored and auscultated in cases of pleurisy, especially on the left side. Suppurative pericarditis may compress the lung and pleura and induce symptoms suggesting purulent pleurisy, but the attenuation or disappearance of these signs when the patient is placed in the knee-chest position, he declares, aids in differentiating. The smaller the child the narrower the chest, and the more chance for compression of the lung with a pericarditic process. When a child has severe heart disease be cautious in affirming the existence of tuberculosis no matter how extensive the râles. Even a positive response to the cutaneous tuberculin tests may indicate merely some minute tuberculous lesion elsewhere; a negative response is more instructive. As children do not expectorate, as a rule the evolution of the affection is often the only clue to its real nature He cites a number of instances of the various types including two cases in which extreme hypertrophy of the heart caused phenomena suggesting pleurisy on the right or left side but necropsy revealed merely the compression by the enlarged heart. In nearly all the cases cited the condition had been erroneously diagnosed. As the heart is the causal factor in the syndromes, treatment should be directed in this line When the heart is much dilated, the pulmonary veins empty themselves only imperfectly, the innervation suffers and a superposed accidental infection entails serious functional disturbances. Restoration of the heart balance by appropriate measures, however, corrects the other disturbances.

66 *Venous Asystole with Hypertrophy of the Left Heart and Stenosis of the Right Ventricle S Bernheim
67 *Infantilism as Result of Malarial Infection. H. de Brun

66 **Venous Asystole with Hypertrophy of the Left Heart and Stenosis of the Right Ventricle.**—Bernheim gives the details of ten cases, all in adults between 25 and 61 years old, in which the left ventricle was much dilated with stenosis of the right ventricle. The lesion was a relic of aortic endocarditis in one case, in two it was due to an aortic valvular lesion, in three to atheroma of the aorta and in four to arteriosclerosis; in one case it was accompanied by interstitial and in another by tuberculous nephritis. In one case the patent Botallo's foramen was responsible for the dilatation of the ventricle; in six cases there was concomitant hypertrophy. This material, he states, shows the frequency of venous asystole with hypertrophy of the heart without degeneration of the muscle. It is the consequence of insufficiency of the right heart from stenosis, and this stenosis is produced by hypertrophy of the intraventricular septum which protrudes as a convex dome into the right cavity. He gives an illustration of the typical pathologic anatomic findings which were alike in all these cases. His clinical experience is still wider. The chief clinical sign of the mildest form of the condition is slight venous congestion with cyanosis of the face and enlargement of the jugular veins. The next stage is a more pronounced venous stasis with enlargement of the liver, the kidneys being of the cardiac type, with edema, but the lungs and respiration are still comparatively normal. In the third stage both the greater and lesser circulation show marked stasis and there is complete asystolia. The condition is frequently erroneously diagnosed, he asserts, as pulmonary emphysema with dilatation of the right heart; there may be actually a little

concomitant emphysema or complementary congestion of the lower part of the lung. Differentiation is most difficult when the excentric dilatation is mainly at the expense of the right ventricle, the vertical diameter of the heart not being notably enlarged. If the apparent hypertrophy of the left ventricle induces stasis only in the greater circulation, the thorax retaining its normal respiration and resonance, the trouble is sure to be stenosis rather than dilatation of the right ventricle.

67. **Malarial Infantilism.**—De Brun writes from Beyrouth reporting forty cases of children or youths of pronounced infantile type, weak and mentally backward. All had had chronic malaria since early childhood and part of the disturbances were evidently the result of the action of the malaria on the thyroid, suprarenals, or hypophysis. The small size, the absence of virility and the infantile genitals suggest that thyroid treatment might prove useful in such cases, and he will later report experiences in this line.

Semaine Médicale, Paris

October 26, XXX, No. 43, pp. 505-516

68 *Abortion. R. De Bovis.

68. **Abortion.**—De Bovis comments on the rising tide of abortions; the number of abortions requiring treatment in the public hospitals of Paris is said to have tripled during the last few years; Treub estimates the criminal abortions as 10 per cent. of all observed in Amsterdam and others there estimate the proportion up to 33 per cent.; at Utrecht, nearly 14 per cent.; at Groningen, 24 per cent., and de Bovis cites several American authorities and others to show the increasing importance of this subject. He warns against making a local examination of a woman threatened with abortion. If absolutely compelled to make an examination, he says, the finger should never be introduced until after the external genitals have been prepared as for a vaginal hysterectomy; otherwise, he says, puerperal infection is likely to ensue sooner or later and the physician alone will be responsible for it. If there is serious hemorrhage he insists on absolute repose with the patient lying flat; quiet is indispensable; if it cannot be obtained at home the patient should be sent to a hospital. If the hemorrhage persists and the physician is morally sure of the death of the fetus, curetting is in order, but there is no hurry, de Bovis says. He has had patients with hemorrhages for a month, one for four months and one for five or six months, and yet the pregnancy progressed to the birth of a living child. On the other hand, one patient insisted on being at once curetted and she died in a few hours from uncontrollable hemorrhage. The temperature will show when the ovum has separated sufficiently. When the patient is kept in an aseptic condition, that is, without local examination or other maneuvers, and hot douches are given only in numbers sufficient to combat alarming hemorrhage, the temperature keeps within normal range. Careful watching may show a slight rise; at the same time slight hemorrhage may recur or a very slight fetid odor may be noticed in the secretions. These signs show that the fetus is dead, that the placenta has become a foreign body and that the uterus is trying to expel it. This is the time for curetting if spontaneous expulsion does not rapidly follow. At this time the operation is easy and without danger, he says. In case of primary uterine infection with temperature above 38 C., the curette should be used at once. He remarks that it is easy to order injections at 45 or 48 C. (113 or 118 F.), but that they are generally given tepid and thus only aggravate the tendency to hemorrhage. Never forget, he reiterates, that each douche should be preceded by a careful toilet of the external genitals. In regard to curetting, he advises waiting until the uterus contracts, curetting gently during the period of relaxation after a contraction, and using the largest curette possible. The point is to curette at the moment when the placenta is almost entirely separated and the uterus offers a thick and resisting wall. Perforation may well be feared when there is infection in the uterus, for then one's hand is forced and the curetting may be done while the placenta is still too firmly adherent.

Berliner klinische Wochenschrift

70. **Differentiation of Albumin by Anaphylaxis Test.**—Friedberger reports research which seems to confirm his view that anaphylaxis is an extremely acute form of infection and that infection is merely a milder, more protracted form of anaphylaxis. He has succeeded in producing in animals the typical symptoms of bacterial infection by repeated injections of small amounts of alien albumen; a single large injection induces the symptoms of anaphylaxis. The most striking characteristic of the latter is the sudden drop in temperature while the most striking characteristic of bacterial infection, perhaps, is the continuous or remittent temperature, and this can be induced at will by repeated small injections of the same substance which in a single large dose induces the anaphylactic shock. He has worked out in this line a method for forensic differentiation of albumin which, he states, is constant and more sensitive than any of the tests hitherto in vogue, not excepting the deviation of complement and precipitin tests: The standards for intravenous injection of sheep serum in the guinea-pig, for instance, are 5 c.c. for the fatal dose; 0.5 c.c. for the dose inducing the drop in temperature; 0.01 the dose below which the temperature does not drop; 0.005 the dose which raises the temperature, and 0.001 c.c. the dose below which the temperature is not modified in any way. Subcutaneous injection of 0.01 c.c. of sheep serum confers anaphylaxis on the guinea-pig, so that intravenous injection two weeks later of one-thousandth of the standard doses mentioned above has the same effect as the above dosage in the unprepared animal. That is, 0.005 c.c. proves fatal; 0.0005 c.c. is the limit dose for the drop in temperature; 0.00001 c.c. the limit below which there is no drop in temperature; 0.000005 c.c. the fever-inducing dose, and 0.000001 c.c. the limit dose below which there is no change in temperature.

71. **Anaphylaxis and Internal Secretions in Connection with Hay-Fever.**—Hoffmann regards the thyroid as the accumulator for the vagus and the suprarenals for the splanchnic domain. Hyperfunctioning of the thyroid makes the vagus more irritable and thus favors the development of bronchial asthma. Hay-fever he explains as a condition of special sensitiveness to alien albumin, and thyroid hyperfunctioning is a powerful predisposing factor. Among the arguments in favor of this view are the occurrence of dermographism and urticaria in both hay-fever and exophthalmic goiter; the frequency of a tendency to goiter in hay-fever victims; the cure of all tendency to hay-fever in one of his patients, a chronic hay-fever victim, by operative removal of a goiter; the reflex conjunctival hyperemia, etc. induced in both hay-fever and hyperfunctioning of the thyroid by tickling the nasal mucosa; the resemblance between the syndrome of hay-fever and that of acute iodin poisoning, and, finally, by the similarity between the response on the part of the skin and temperature to subcutaneous injection of pollantin in hay-fever patients and of thyroidin in exophthalmic goiter. The main points in treatment of hay-fever are thus, he says, to check the functioning of the thyroid and to reduce the irritability of the nasal mucosa. Strumectomy is the most radical measure, but Roentgen-ray treatment may also prove effectual in checking thyroid hyperfunctioning. The irritability of the nasal mucosa can be combated by topical measures, by a constricting band around the neck, by injection of alcohol into the nerve or by severing the nerve, or by massage or cauterization of the

nasal mucosa or other measures. His clinical experience has been very favorable with treatment based on these principles, the guiding idea being that hay-fever—pollen disease—is due to a special susceptibility to an alien albumin contained in the pollen of certain plants, plus thyroid hyperfunctioning.

73. **Drug Eruptions as Anaphylaxis.**—Bruck states that a physician found that aphthæ developed on his lips and tongue every time and almost immediately after he took a dose of antipyrin. He consequently refrained from using this drug for sixteen years; then he took another dose of 1 gm. and immediately the old aphthous reaction developed at once. Experiments with his serum on guinea-pigs confirmed the assumption that his idiosyncrasy to antipyrin and its derivatives is an actual anaphylactic phenomenon, and that the anaphylaxis could be transmitted to animals by injection of his serum.

75. **Treatment of Tuberculosis by Inoculation of Skin with Tuberculin.**—Pöppelmann has applied the v. Pirquet technic for systematic administration of tuberculin, and lauds its numerous advantages over the more complicated usual technics *while it seems to surpass them in the mildness, constancy* and more gradual action of the tuberculin incorporated in this way. He dips the blade of the scalpel in the "old" tuberculin and spreads the droplet thus taken up on the skin of the upper arm. Then he scratches the skin with a single stroke of the scalpel, the same as for ordinary vaccination. After all subsidence of the local and general reaction, he makes another scratch, crossing the first. The third time he adds two more scratches, thus forming a double cross; the fourth time two more, forming a lattice-work of scratches, adding two each time. He gives some typical case-reports to show the simplicity and convenience of the technic and its special therapeutic advantages. It seems evident, he declares, that the skin possesses certain biologic factors which enhance the curative and tonic action of tuberculin given in this way. With this technic, he says, tuberculin treatment becomes possible in everyday routine practice.

Medizinische Klinik, Berlin

81 Cardiac Neuroses. (Die sogenannte Herzneurosen.) M. Herz. Commenced in No. 42.
82 Lung Suction Mask in Treatment of Asthma. (Physikalische Behandlung des Asthma bronchiale.) E. Kuhn. Commenced in No. 42.

78. **Ehrlich's "606" in Syphilis.**—Weintraud concludes from his experience in 250 cases that syphilis is not definitely cured by a single injection of "606" and that no benefit can be anticipated from it in tabes. The syphilitic infection may injure a predisposed nervous system to such an extent that even the most thorough treatment may not prevent the development of tabetic spinal cord disease. In a few of his patients the new remedy failed to display any therapeutic action, and the Wassermann reaction persisted unmodified in many of the patients; in others, after a negative phase, it became positive again in a few weeks. The negative phase after treatment with "606," therefore, does not indicate a complete cure any more than after mercurial treatment. Recurrence was observed in fourteen out of eighty cases of recent and secondary syphilis. In only thirty-seven out of seventy-seven patients did the Wassermann reaction become permanently negative. In three cases the Wassermann reaction persisted unmodified even after a second and third injection of "606." He does not regard it as probable that the permanent results will be any better from increased dosage; in his experience intravenous infusion of the drug—which brings the whole organism under its influence more thoroughly—was not followed by a permanent cure any more than with the other technics. It seems that the body reacts as promptly and extensively to a small as to a large amount of the drug, and this reaction is the *chief aim in the treatment* of human beings, while in animals the aim is to kill all the spirochetes at one stroke. Repetition of the doses may prove effectual as with mercury. None of the symptoms in his twenty cases of tabes seemed to be influenced by the "606" but it displayed great efficacy in patients refractory or intolerant to mercury and iodid. There is grave danger, he continues, that physicians and the public will regard the problem of the cure of syphilis as too simple and as already solved. It must be reiterated that the cure of syphilis in man is a far more complicated process than the cure of experimental syphilis.

79. **Antagonism Between Infectious Diseases and Cancer.**—Schmidt has been much impressed with the fact that in 241 cases of carcinoma, ninety-nine of the patients had never had any infectious disease, either in childhood or adult life, and that forty-nine had had only one of the children's diseases and no infections later in life, and fifteen only one infectious disease in adult life. Only three of the total 241 patients had passed through two or more infectious diseases since puberty; 180 had had no children's diseases, and 140 no infectious disease in adult life. His cancer patients had thus not had *their organisms modified by infectious diseases, consequently* the conclusion is evident that the infectious processes must modify the constitutional soil in such a way as to reduce the predisposition to cancer. He suggests that modern prophylaxis of infectious diseases, steering away from the Scylla of infection is liable to strike on the Charybdis of cancer. He calls the number of infectious diseases the individual has passed through, the "infection index," and urges others to study whether this index is as strikingly low in their cancer cases as he has found it at Vienna.

83. **Stimulation of the Circulation by Differential Pressure in the Lungs.**—Bruns expatiates on the important part played by the respiration in promoting the circulation, and states that this influence can be enhanced by differential pressure procedures. The method he has found most convenient is the artificial rarefaction of the air breathed into the lungs. This he realizes by having the patient breathe freely through a mask into a large tank in which the pressure of the air has been reduced by 8 to 10 c.c. water. The respiration-rate increases by 4 and the pulse rate by 8 to the minute, while various tests reveal that the procedure induces a rapid and ample aspiration of venous blood upward. The arteries also feel the stimulating effect of the more rapid emptying of the veins and a secondary increased arterial flow toward the periphery is rendered evident by the plethysmograph. The procedure promotes the return flow of the venous blood and it is thus specially indicated, he states, in case of weakness of the heart action from impeded respiration, in heart disturbances from kyphoscoliosis, with pleuritic adhesions, emphysema with rigid thorax and atelectasic processes in the lungs. It may be indicated further in case of weak heart action in the obese *and anemic, in persons in sedentary occupations and in*

myocardial lesions from preceding overexertion The contraindications are the same as for any physical measure, advanced failing compensation with much edema aneurysm, thrombosis and impending embolism. Even with failing compensation, patients bore the application of the procedure for fifteen minutes at a time without disturbance, no vertigo, palpitation or dyspnea being observed, the relief was so pronounced that the patients asked to have the course of treatment continued

85 **Alcohol Infiltration of Nerve in Laryngeal Tuberculosis**—Roth extols the advantages of injection of alcohol to deaden the superior laryngeal nerve and thus free the patients from the pain in swallowing which torments the victims of laryngeal tuberculosis. He has applied the measure in thirty three cases and the effect was the immediate suppression of the pain in all but one case, the analgesia persisted for from one to twenty one days, averaging about a week Repetition of the injection does no harm and the patients clamor for it In one case he repeated the injection five times. the effect seems to be felt earlier and to persist longer as the injections are repeated He disinfects the skin with alcohol and mercury bichlorid, and presses the larynx toward the side of the tenderest point and introduces the needle at this point for about 1 5 cm and then twists the needle upward and outward, a sharp pain radiating to the ear shows that the nerve has been reached Then about 1 gm of 85 per cent alcohol warmed to 45 C in the water bath, is cautiously injected The typical sensitive point is easily found between the hyoid bone and the ala of the thyroid cartilage, where the internal branch of the superior laryngeal nerve pierces the thyrohyoid membrane This branch is the sensory nerve for the inside of the larynx and trachea

86 **Heart Disease Following Trauma.**—Beckhaus' experience with three cases has shown that myocarditis may develop insidiously after a fall on the left chest or contusion of this region Two of his patients were men over 50, previously healthy. The third patient was a younger man, and the heart was found apparently sound four months after the accident, the myocarditis not developing symptoms until after this interval The heart disease was much milder in the case in which the patient had been treated by a month of repose after the accident In all cases of injury affecting the left chest he says, special attention should be paid to examination of the heart and the possibility of an organic affection later should not be forgotten Otherwise the symptoms when they develop are liable to be ascribed to neurasthenia or hysteria

90 **Fatality After Injection of Ehrlich's "606"**—Ehlers injected the drug according to the Wechselmann technic The patient was a man of 40 with paralytic dementia which had considerably improved under psychiatric treatment, so that he was able to walk and read the papers and understand part of what he read He had had two apoplectiform attacks previously, one two years and one five weeks before the injection of "606" The injection was not followed by any local reaction but progressive symptoms on the part of the nervous system developed, tremor, sweating crises and weakness, and the patient died the fifth day of progressive heart weakness No cause for the fatality could be discovered at necropsy except acute parenchymatous degeneration of the organs

106 *Ehrlich's '606 in Syphilis R Polland, R Knauer and J. Furth

98 **The Esophagus with Enlargement of the Heart.**—Kovacs and Stoerk give a number of illustrations showing compression and extreme displacement of the esophagus liable to occur with dilatation of the heart As the compression is by a soft and yielding body, the flattening and displacement have little practical importance as there is no subjective disturbance

101 **Ehrlich's "606" in Syphilis**—Pick states that since his first publication on this subject recurrence of symptoms has been observed in some of the cases previously reported as cures He encountered six refractory patients among the 200 treated

103 **Solidified Serums and Antigens**—Stokel has found that serums and antigens will keep perfectly when mixed with sodium sulphate to bind the water One c c of immune serum mixed with from 0 7 to 1 gm. of calcined sodium sulphate is taken up and the whole solidifies and can be pulverized The total weight of the mass is from 1 7 to 2 gm and, dissolved in 100 c c of distilled water, produces an isotonic fluid, corresponding to a salt content of 0 7 to 1 per cent and a dilution of the active serum to 1 per cent His experiences have confirmed the great convenience and the reliability of this technic

106 **Ehrlich's "606" in Syphilis**—Polland and Knauer found the Wassermann reaction positive in twenty-five out of twenty eight patients after complete subsidence of all symptoms. One patient had high fever accelerated pulse and retention of urine for seven days after injection of the "606" by the old methyl alcohol technic which has since been abandoned. They encountered several refractory cases Furth calls attention to certain peculiarities in the recurring and secondary symptoms after the use of Ehrlich's remedy. It is evident, he says, that clinicians will have to make a distinction between the manifestations of syphilis after mercurial treatment and after treatment with "606" The pathology of syphilis is about to be revolutionized, he thinks, along with the prognosis

117 Contra-Indications for Intravenous Saline Infusion. R. Bertelsmann.
118 Management of the Colon After Resection and Suture. C. Bayer.

116. **Treatment of Exstrophy of the Bladder.**—Roloff's patient was a healthy, stout girl of 6. He cut out a segment of the bladder wall containing the mouths of the ureters, and then, through a laparotomy incision, slit the bowel at the sigmoid flexure. Twisting the segment of the bladder forward and upward, making a turn of about 180 degrees, he sutured it in the slit in the bowel. The uterus rested in the angle formed by the ureters and trigonum and was fastened here with a few sutures. The functional result was perfect from the first; the child is continent and there has been no disturbance to date. He suggests that this technic might be improved on by suturing the segment of bladder into a stretch of cecum plus some of the ileum, after exclusion of this section of the bowel, twisting the appendix around and suturing it in the rectum. Ascending infection from the bowel would be impeded by Bauhin's valve even if it could pass upward through the narrow appendix, the constant flow of urine being all the other way. The operation might be done at two sittings, the appendix being thoroughly sterilized and prepared during the interim.

120 Operative Treatment of Large Postoperative Ventral Hernia. S. Lindqvist.

119. **Death of Parturient Allowed to Get Up Early.**—Scherer states that he has been able to find records of only two or three fatalities from the custom of allowing parturients to get up earlier than has been the rule until within the last year or so. But he here reports a case in which the woman was allowed to get up and sit in a chair for half an hour on the third day after abortion at the third month. The temperature ran up the next day and fatal thrombosis developed in the pelvic veins. He remarks that if the patient had not left the bed so early the thrombosis might not have developed or the localization of the process might have been more favorable and the outcome better if the patient had been kept in bed longer. Among the 9,257 deliveries at the Budapest clinic, with which he is connected, thrombosis developed in only thirty-four cases, that is, in 0.36 per cent., and the outcome was fatal in only one of the two cases complicated by pulmonary embolism. On the other hand, this case of fatal thrombosis occurred in the small group of 200 parturients allowed to get up earlier than the usual rule.

123. **Early Diagnosis of Gastric Cancer.**—Benacchio reviews the various methods in vogue for detecting incipient gastric cancer, and adds that they mostly require special skill and experience for the technic of the tests and interpretation of the findings. Consequently the general practitioner should refer his patient to the specialists for these tests when he has the slightest suspicion that the patient may be developing gastric cancer. This is his task, and on his performance of this task depend the fate of the patient and the progress of science in this line.

THE ETIOLOGY OF THE PTOSES AND THEIR RELATION TO NEURASTHENIA*

EDWARD REYNOLDS, M.D.
BOSTON

The application of surgical treatment to neurasthenia implies a belief that in the given case the nervous condition is the product of local suffering; and the attainment of the ultimate object of course implies the complete relief of the local suffering as the first step in the process of cure. It therefore seems logical that any discussion of the surgical aspects of neurasthenia should begin by consideration of the results which may be expected from the relief of the local symptomatology.

In this particular subject of the connection between the ptoses and neurasthenia we are met at the outset by the significant fact that after many years of collective experience in the surgical treatment of the ptoses, the discussion about the end results of operation is almost as active and as much a moot question as it was ten years ago.

It is further significant that a review of the literature of this subject during the past ten years shows at once that the controversy on it has been conducted almost without exception along the lines of advocacy of differing technical methods, with an almost entire neglect of any apparent interest in the cause of the lesions.

Now the whole history of surgical progress shows that the long persistence of such a technical question without satisfactory settlement always implies an unsettled pathology or etiology, and that such a technical controversy is usually brought to an end only by some advance in our theoretical knowledge of the cause of the lesions, after which the decision about methods is usually prompt and easy. Thus the selection of the etiology of the ptoses as the subject of the opening paper in this discussion has the double justification that it is at once the line of discussion which promises the most far-reaching results, and that which has been least worked out.

The first and most important point in the etiology of the ptoses is almost axiomatic. It needs no argument to show that they are never primary lesions, but are always secondary to some preexistent mechanical cause, either (a) in the failure of the natural supports of the organ, or (b) in the existence of some abnormal force antagonistic to the efforts of supports of normal strength. These two classes of cause now demand our further consideration.

The ptoses due to weakness of the supporting structures are far the best understood and may be considered first. Ptoses due solely to such weakness are, however, far less comon than has been generally understood.

Much that has been written in the past on the subject of ptosis would lead one to believe that a spontaneous relaxation of the supports of some one organ was a common phenomenon. So far as my observations go they tend to show that this is an erroneous view and that the muscular relaxations are always general in their character. Cases which appear to be due to localized relaxation of the supports of a single organ will always prove on closer analysis to be due to an abnormal force which is pushing or pulling that organ out of position and which has overcome the tonicity of its natural supports.

The importance of general, constitutional, muscular relaxation, and loss of fat in the production of generalized ptosis is well understood; but so important a fact as this must not be lightly passed over.

It is, moreover, important to realize here that rapid loss of fat is by all odds the most important element in the causation of the class of cases in which the ptosis is the result purely of passive lengthening of the normal supports. The tissues in these relaxed cases have usually been previously stretched by the deposition of fat within them, and if this is suddenly lost lengthening of the so-called ligaments is inevitable.

In treatment it is most essential to recognize that in *this class of cases operative treatment is almost never* indicated. We must treat them in accordance with their causation. They will usually obtain relief under treatment directed toward the improvement of general muscular tone and increase of nutrition, and will never obtain satisfactory relief without such general improvement. Operative treatment should be adopted only in the very few instances in which the local symptoms which are the product of the ptosis so far interfere with digestion as to render it difficult to secure proper nutrition without it, and even then it must be remembered that subsequent improvement in nutrition and muscular tonicity is the ultimate object of the operation, and that every therapeutic device at our command should be directed toward its attainment.

The causation and management of ptoses of this first class is, however, generally well understood, and belongs to the domain of accepted surgical principles, but the theorem that there are many cases of ptosis which are primarily due to the existence of forces which are antagonistic to the normal supports of the viscera has only recently attracted attention. I believe that many, if not most, of our failures in the operative treatment of ptosis occur in cases of this second class, and are due to adoption of routine operative measures without previous investigation of the cause of the individual ptosis, and often in defiance of continuing forces which directly dispose to its reproduction. The discussion of these predisposing or directly causative anomalies, and of the surgical measures appropriate to their correction, forms, then, my main theme.

---

* The opening paper in a discussion on "The End Results of Operations for Ptosis" at a combined meeting of the American Surgical and American Gynecological Associations.

The forces which tend to produce ptosis may be of either local or general origin, and must be considered in detail, those of systemic origin and influence naturally coming first.

GENERAL STATIC FORCES

During the last four or five years my attention has been especially directed to a study of the influence of general static or mechanical conditions on the positions of the abdominal and intrapelvic organs, and much of my time has been given to a prolonged experimental, and, of late, clinical study of this subject in collaboration with Dr. R. W. Lovett. Our experimental studies as bearing on the relation between balance in the erect posture, backache, and the intrapelvic lesions, have been recently published,[1] to which paper I must refer in support of many of the statements which I shall make here. During the past year clinical papers bearing on the same subject as connected with ptosis have been published by several widely separated observers.[2] Dr. Lovett and I are now actively engaged in the collection of cases and the tabulation of symptoms and conditions for the purpose of studying these states from a clinical standpoint, but, significant as we think that this study is proving in everyday clinical work, the number of cases which we have observed with accuracy is not yet sufficient for the publication of exact results. I must be content here with a merely preliminary, and I hope suggestive, outline statement of a few of the main facts which we have observed.

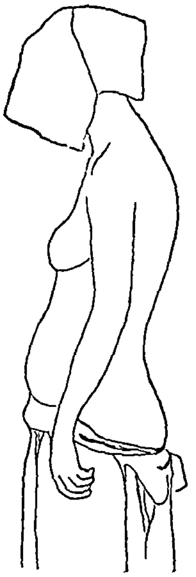

Fig. 1

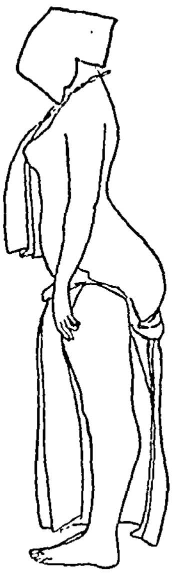

Fig. 2.

Fig. 1.—The round-shouldered, hollow-backed position. An outline reproduction of a photograph from life. Not an extreme example.

Fig. 2.—The overfeminine figure. An outline reproduction of a photograph from life. Not an extreme example.

The variations which we have grown to think important are partly functional and partly congenital, or compubertal variations of skeletal form. First and perhaps most important among them is the attitude known to orthopedic surgeons as the round-shouldered, hollow-backed position illustrated in Figure 1. In this attitude the center of gravity is carried too far forward for easy maintenance of balance, and the capacity of the upper part of the abdomen is decreased by the forward droop of the upper dorsal spine and the descent of the ribs, while the relaxation of the anterior abdominal wall produced by the approximation of the ensiform cartilage to the pubes permits the formation of a pot-belly, with consequent increase in the capacity of the lower abdomen. During the gradual supervention of this abnormal attitude the contents of the upper abdomen necessarily tend to rearrange themselves downward in adjustment to the altering pressures, while the unduly forward position of the lumbar vertebræ, from the anterior face of which the intestines depend, leads to the impaction of their dependent coils against the anterior wall of the abdomen and pelvic cavity.

In the normal attitudes the impact of the intestines is directed against the posterior surface of the uterus and tends to hold it forward, but when, as in this attitude, the intestines necessarily slip into and out of the pelvis along its anterior wall they must sooner or later enter the uterovesical pouch during descent, and so force the uterus and its adnexa backward.[3]

This attitude is present in a surprisingly large fraction of all ptoses, and is causative toward the ptoses of all the viscera; since I have been led to look for it I have become shocked and ashamed at the blindness which has led to my utter failure to even see so noticeable a phenomenon during all the previous years in which I have been dealing with them. I think that this will be the experience of any operator who has not been previously impressed with the importance of this attitude.

If in such a case an operation for the relief of a ptosis of any one of the viscera is performed without correction of the vicious attitude the persistence of the latter and its consequences is of necessity a continuous force against the permanent endurance of the result. This posture is probably the product of a functional loss of correct balance and is due to factors the relative importance of which we are as yet unable to isolate with certainty.

The second abnormal posture of which we feel able to speak with some certainty is a developmental variation which has been heretofore neglected, but which we have ventured to describe as the overfeminine figure, and which is illustrated in Figures 2 and 3. These women have more or less overextended knees, large hips, hollow backs, and usually somewhat small waists and prominent busts. They are apt to become fat and to have noticeably small hands and feet. Their center of gravity is habitually carried too far forward. In them the inclined position of the anterior abdominal wall and the forward inclination of the lumbar spine tend again to impact of the intestines against the anterior pelvic wall, and consequently to displacement of the uterus. We have not, however, seen reason to think that this posture is often associated with the ptosis of the upper abdominal viscera, except when these are due to the dependent drag of a pendulous abdomen, which is, however, certainly an especially common accompaniment of this figure in middle life.[4]

[3] It has long been recognized that the intra-abdominal pressures correspond closely to hydrostatic laws owing to the nearly equal specific gravity of all the contents; but upon this very basis it is evident that intestinal coils which contain gas will tend to rise, and thereby displace downward those which contain fluid, hence the constant change in position of individual portions of the intestines during peristalsis.

We have worked so long on this subject that we are very anxious to put forth no statements which are not likely to be substantiated by further observations. We do already feel confident that the two variations of posture illustrated are of real importance in their relations to the ptoses, and that their habitual correction will lead to a higher degree of success in the operative treatment of ptosis than is possible without it. We have seen such correction of attitude lead to the relief of symptoms in cases which had previously been operative failures, and we have seen it yield both anatomic and symptomatic success without operation, in cases which we should formerly have considered operative.

Fig. 4.—Diagrammatic representation of a weight suspended by a sling.

Much curious information is also coming to hand on the relation of the lateral inequalities and distortions, such as lateral curvatures produced by short leg or unequal pelvis, *e. g.*, to the disturbances of anteroposterior balance, and to the production of unequal abdominal strains and ptoses; but, although we are frequently obtaining clinical relief in otherwise obstinate intrapelvic and upper abdominal conditions by associated treatment of these distortions, all this is also too little worked out to be fit for more than the merest mention here.

Both of the attitudes illustrated are largely correctible. Their treatment lies in (a) gymnastic exercises, graduated outdoor exercises, improvement of nutrition and similar methods; (b) in mechanical aids to balance and posture. The first class of treatment I shall not enter into, because, important and all-essential as it is, its methods are well established and I have nothing new to offer on it, but on the mechanical therapeutics of the trunk our experimental work has thrown some light which we think has been borne out by our clinical experience.

We believe that not only in the functional backaches, but also in the ptoses the essential factor in mechanical treatment is the rectification of the incorrect posture which is so constantly a factor, and apparently a determining factor, in their causation, and which is itself always dependent on an abnormal position of the center of gravity. Our experimental work has shown that this abnormality can be corrected by appliances far more simple and comfortable to the patient than many which are in use, and our clinical experience leads us to believe that equally good results are attained thereby.

The subjects of ptosis are almost invariably neurasthenic, and we believe most emphatically that in their treatment by mechanical appliances the first and prime necessity is that the apparatus used should be comfortable. The surgeon who fixes attention on a local condition and subjects a neurasthenic who is annoyed by a ptosis to prolonged and continuous discomfort from straps and steels does harm rather than good. He too often substitutes a greater discomfort for the lesser one which he is attempting to relieve. The great advantage which the therapeutic corset has over the complicated harnesses so often employed is that it can be made, and should always be made, a distinct comfort to the patient from the moment it is applied. It may be said of the corset, as it has long been said of the pessary, that if it is not comfortable it is not efficient, and with almost equal truth, that if it is not comfortable it is doing harm.

Extreme cases may demand extreme treatment, but we believe that a corset properly contrived to support the lower abdomen is for most cases the simplest, least harmful and most generally effective appliance, especially if it is backed up by proper shoes.

It is certainly true in my experience with nephroptosis that corsets, belts and pads adapted to make direct pressure on or below the prolapsed kidney have proved far less effective than those which are fitted to restore the normal direction to the general intra-abdominal pressure, both by properly directed compression and by restoration of balance.

Lack of space forbids me from entering fully into mechanical therapeutics here, but a few words descriptive of the mechanism by which the therapeutic corset chiefly corrects attitude may be of interest. As has been said, the leading general characteristic of all these attitudes is the carriage of the center of gravity of the body too far forward, with backward displacement of the buttocks and forward displacement of the upper part of the trunk. We have been able to demonstrate experimentally that the use of high-heeled shoes tends to sway the body as a whole backward from the ankle; also that certain forms of corsets, as well as other forms of apparatus, to which we have only referred incidentally in our publications, tend to bring the buttocks forward and the shoulders back, and this latter movement is effected by a mechanical principle which is also perhaps of sufficient interest to be mentioned here.

It is a general rule in mechanics that the action of opposing forces at rest is always opposite and equal, so that the downward pressure on the lower *end of a sling*

---

[4] It is important to distinguish between the rotundity due to increased fat with increased abdominal pressure, and the protuberance due to true relaxation of the abdominal walls with decreased or even negative intra-abdominal pressure.

(Fig. 4, A) in which a weight is suspended is of necessity exactly equal to the traction on the upper end of the sling (Fig. 4, B); thus, if the weight of the pendulous abdomen is suspended by a belt or therapeutic corset which obtains its bearing from the posterior surface of the sacrum, that weight may be regarded as having been transferred from the anterior to the posterior side of the lower portion of the trunk. It is, in fact, mechanically equivalent to a weight placed on the sacral region: but if a weight is so placed on any portion of the posterior surface of the body it carries the center of gravity of the whole mass so far backward that the model must either fall backward or readjust the center of gravity;[5] and if the weight is placed on the sacrum the necessary change is, in fact, effected by carrying the hips forward.

If, however, the hips were carried forward without alteration of the position of the trunk the center of gravity would at once be carried so far to the front that the subject would fall on her face; hence the forward motion of the hips superinduced by the weight on the sacrum is of necessity complemented by a backward motion of the shoulders. In practice as well as in theory the first among the many effects of the therapeutic corset is a readjustment of posture by moving the hips forward and the shoulders back, *i. e.*, the assumption of an erect posture. It is to be noted, too, that this straightening of the dorsal spine and squaring of the shoulders with consequent elevation of the ribs and expansion of the chest is effected by the patient's own muscles under the influence of an instinctive effort toward the maintenance of balance. It is an active and natural return to a desirable attitude under the influence of the change in the abdominal pressures and in the position of the center of gravity. As such it is therapeutically far more desirable than the enforced and passive assumption of the same attitude in opposition to the natural instincts which is produced by shoulder-straps and rigid back-braces.

One word of caution must be inserted. We have learned by experience, and considerably to our surprise, that the change of dorsal attitude so induced may easily be made so extreme as to cause new dorsal and cervical aches if it is pushed too rapidly. The first corset should not be so cut or adjusted as to produce all the effect that is ultimately to be desired. A moderate change of attitude is all that is at first permissible, and adjustment to this new position should be effected by graduated exercises before more is attempted.

Another great advantage of the therapeutic corset as a mechanical corrective is that, if properly made, it restricts the motion of the body above the waist exceedingly little and permits free play to the dorsal and scapular muscles throughout the patient's day.

In conclusion of this section I may say that no one can appreciate more fully than Dr. Lovett and I the elementary character of all that we are as yet ready to say on this subject, but we believe that our experiments and observations have already gone far enough to warrant our belief in the importance of posture in this as well as in some other relations; moreover, this belief is supported by the publications already alluded to. In practice, too, we are obtaining so much satisfaction that we feel confident of the importance of this subject. Many ptoses are dependent, as is yet to be said, on conditions which can be remedied only by operation; many chronic backaches also are dependent on anatomic lesions which can be treated radically only by operation, but the great majority of both affections have a general static element in their etiology and demand its recognition in their treatment. In especial we may say that there are but few chronic backaches which cannot be remedied if both elements in their etiology are taken into consideration.

The abdominal surgeon must learn that in a large proportion of cases of the nature under consideration he must utilize the aid of mechanical and gymnastic therapy if he wishes complete results. The orthopedic surgeon also must learn that ptoses and backaches are by no means universally of purely static origin, and that whenever a case of this nature fails to react promptly to mechanical and gymnastic treatment an examination of the abdominal and intrapelvic organs should precede all further orthopedic effort. In many of these cases the two specialists must work together if really satisfactory results are to be attained.

LOCAL ABNORMALITIES

The static abnormalities are general in their action and may effect the relations of any or all of the abdominal viscera. The local causes of ptosis, now to be spoken of, are, on the contrary, individual to each organ. They are probably of equal importance throughout the abdomen, but in treating of them I propose to restrict myself here to the local causes of the intrapelvic ptoses only, since it is in that portion of the abdomen that these local causes are most easily worked out, and on the local causes of the ptoses of the upper abdomen I am not yet ready to speak.

The local causes of the pelvic ptoses are to be found in the inflammatory lesions, trauma, and some developmental anomalies, each of which with its treatment must now be taken up by itself.[6]

In this connection it is well to remember that the retrodisplacements are in themselves ptoses and are, moreover, no more than the first stage in complete ptosis of the genital organs. For the purposes of this paper, then, all the displacements of the uterus and its adnexa may be fairly considered as a single group of essentially similar lesions which can be dealt with here as a whole; and for economy of space they will be so treated.

In the pelvic ptoses due to obstetric trauma and inflammatory diseases the static predispositions are again of some importance, and at the risk of repetition I must again briefly refer to them here.

The operative treatment of the ptoses due to obstetric trauma is mainly concerned with the repair of lacerations, but it is well recognized that extensive obstetric trauma is sometimes followed by curiously little loss of support, while in other cases extremely slight solutions of continuity are followed by displacement, descensus, or perhaps by complete prolapse, and the explanations offered for these differences in result have not been heretofore wholly satisfactory. I believe that a valid explanation of them is now to be found in the existence, or nonexistence, of the predisposing causes in the individual anatomy. I believe, too, that the search for these causes is all important in the treatment of these cases also, and that their correction will often contribute most satisfactorily to the avoidance of the failures which still too often follow on an operation for prolapse.

---

[5] For suggestions leading to the elaboration of this and many other mechanical points we gladly acknowledge our indebtedness to personal communications from Dr. Ansel G. Cook of Hartford whose instinctive appreciation of the problems of balance is well known to the orthopedic portion of the profession.

[6] Consideration of the ptoses due to the weight of new growths will be omitted here.

Perhaps the most prominent of all the local causes of the pelvic ptoses are the infections of the Fallopian tubes. It is universally recognized that adherent tubes drag the uterus backward and that the separation of the adhesions is the first step in the operation in these cases; the methods which should be adopted for the remainder of the operation constitute the only point in question. I believe that here we must rest on the original cause. When the history and physical examination warrant the belief that the occurrence of an infection in previously wholly normal organs was the only source of a displacement, the separation of the adhesions is a complete removal of the cause, and the operation which best holds the tubes away from the posterior peritoneum is the operation of choice. On the other hand, it must not be forgotten that the displaced genital organs are especially prone to inflammation and adhesions from slight causes, and that ptosis of the uterus and its adnexa, originally simple and the product of other local or general causes, may in time become complicated by inflammatory conditions which overshadow the original causes. In these cases the method of treatment adopted after the separation of adhesions should depend on the original cause of the lesion, whatever that may have been, precisely as in uncomplicated retroversions.

The developmental anomalies are of the utmost importance, since there can be little doubt that the whole subject of ptosis is closely related to that of general underdevelopment and should always be studied in that light. In the absence of the evidence of general underdevelopment the local anomalies are, however, ordinarily in themselves a sufficient explanation for the ptoses, and indicate at most only some modification of the ordinary operative treatment.

Among those developmental anomalies which are efficient local causes of uterine displacement, or ptosis, limited space prevents my mentioning more than the three which I have most frequently seen.

Normally the vagina and rectum separate somewhat below the level of the posterior cul-de-sac: exceptionally they are attached to each other throughout the whole length of the vagina, and even up to its actual attachment on the posterior surface of the uterus. In this anatomic condition the effort of emptying an overloaded rectum necessarily forces the uterus backward and downward, and if this condition is allowed to persist it will almost certainly militate against a good result from operation. It is not an extremely common anomaly, but I have seen it effective in a number of instances, and the possibility of its existence is well worth the momentary inspection which will detect it. If it is found, the separation of the rectum from the upper part of the vagina is easily effected, and should then be rendered permanent by a transverse suture of the incision. This small addition to the operation will in such cases make the whole difference between success and failure; without it the contest between the new mechanical conditions which were brought into being by the operation and the still existent abnormal rectal attachment, which drags the organ backward and downward, is likely to result either in the loss of the anatomic results of operation or, if they persist, in the production of a new pain.[7]

A not infrequent and a very important anomaly which has not attracted so much attention as it should is the persistence into adult life of one of the so-called ileolumbar ligaments which are normally present in the fetus. These structures represent ontogenetically the primitive support of the genital organs, but have disappeared normally in the adult human female. It will be remembered that during fetal life the ovary, like the testicle, descends from its original position in the forward part of the celom to its final position in the pelvis, while at the same time the kidney moves in the reverse direction. These movements are bilateral, but on the right side of the abdomen they are complicated by the descent of the cecum and ileum. They are accompanied and probably facilitated by the development on each side of longitudinal folds of peritoneum containing freely developed smooth muscular fiber which have been described by numerous anatomists[8] under several names (*e. g.*, ileolumbar, lumbo-ovarian, ileo-ovarian, appendiculo-ovarian ligaments).

During a portion of fetal life these ligaments are strong and well-marked longitudinal structures which draw the fundus upward and backward in opposition to the as yet little-developed round ligaments. With the progress of development they relax and permit the formation of the transverse broad ligaments. Eventually the ligament of the left side entirely disappears, while a portion of its fellow on the right side persists permanently. This structure is well known as a fold of peritoneum which originates sometimes in the mesentery of the appendix, sometimes in the mesentery of the ileum, sometimes in both, and from there runs downward to be lost in the general peritoneum at the brim of the pelvis. It has been recommended as a guide to the appendix.

I know of no instance in which the ileolumbar ligament of the left side has been found persistent, but I have seen numerous instances of its total or partial persistence on the right side. It then forms a band, which with its continuation, the utero-ovarian ligament, connects the right cornu with the peritoneum in the neighborhood of the ileocecal valve. When fully persistent it holds the uterus in forced retroversion; this condition is, however, probably rare, I have seen but one instance of it, but its partial persistence is not uncommon. It is then easily overlooked unless the uterus is drawn strongly forward with the intent of searching for it, when it springs into prominence. If it is not detected this effect will of course be produced as soon as the uterus is drawn into anteversion by any operative procedure. It then forms a retro-uterine guy on which the weight of the intestinal coils must necessarily rest when the patient reassumes the erect posture, and persists as a strong element against the success of the operation. My experience, which now covers thirteen years of observation, leads me to believe it a not uncommon anomaly.

---

[7] In this connection note also the recent development of intra-abdominal operations directed against the tissues immediately behind the cervix.

Vallin, Paul: Situation et prolapsus des ovaires, Paris, 1887.

I have also seen some reason to suspect that this anomaly may sometimes be responsible for a ptosis of the kidney, a view which its embryologic significance would tend to support. I have once seen it responsible for a displacement of a portion of the ileum.

If this ligament is found it should be divided and the cut edges of the peritoneum whipped over before any form of suspensory operation is done, care being taken that the division is sufficiently extensive to lead to full relaxation.

Perhaps the most important of all the developmental anomalies is, however, the condition known as anteflexion of the cervix. This lesion, though familiar to every gynecologist, has, I think, not been generally recognized as a cause of retroversion. It is, in point of fact, a developmental failure, a partial persistence of an infantile condition, in which the cervix is held forward by a congenitally short anterior vaginal wall and similarly shortened uterovesical ligaments; but since the cervix is much the most firmly suspended portion of the uterus, a forward fixation of the cervix necessarily tends to a backward position of the body. That the forward position of the fundus which is originally characteristic of anteflexion of the cervix is not, as is usually believed, necessarily due to an organic curvature of the body, is shown by the fact that forward fixation of the cervix is present in an extremely large proportion of all straight retroversions of the uterus, and that in each of these the reposition of the body by operation only restores the overbent condition from which the organ had escaped by straightening out into retroversion. Dysmenorrhea which has been recovered from is often reestablished by such operations.

Lack of space forbids my entering at length into this subject, but my own experience in observation of it has been so conclusive, and already so extensive, that I am confident that any observer who will trouble himself to watch for this condition in his cases of retroversion will become convinced of its importance. Indeed, one has only to watch the effect of temporary anesthesia on uncomplicated cases of anteflexion of the cervix to find that under the muscular relaxation so induced the fundus commonly falls backward, to be drawn forward again when muscular tone returns. It can then hardly fail to be a constant influence towards retroversion.

The condition is easily remedied by a transverse division of all the tissues in front of the cervix. The vaginal wall should be divided transversely with the knife just anterior to its junction with the cervix, the bladder should then be separated from the supravaginal cervix by blunt dissection with the finger, and the tissues on either side of the cervix and anterior to the broad ligaments should be somewhat widely separated by the same blunt dissection. The only bleeding will be from the cut edges of the vaginal wall and will be entirely controlled by the suture, which should be inserted transversely and for elongation of the vaginal wall. The deeper tissues need no attention. The adoption of this simple procedure as a preliminary to the abdominal treatment of retroversion in these cases has much improved my own end results, and I feel sure that this point is an important one.

I believe that the developmental anomalies of the viscera of the upper abdomen form a point well worthy of further study in connection with their ptoses.

In conclusion of my treatment of this first question, *i. e.*, of the local end results of operation, I must permit myself to say that I cannot help feeling, more and more clearly, with each succeeding year of the five which I have now devoted to the pursuit of this subject, that the careful study of the etiology of each case of ptosis promises in the end to clear up much of the confusion which has so long surrounded and still shrouds this question, and to lead to the intelligent adaptation of the form of operation chosen to the needs of the individual case; also that I am becoming persuaded that the detection and correction of auxiliary or predisposing causes before operation is undertaken, and their reasonably continued treatment after operation has been performed is even by itself of far more importance to both anatomic and therapeutic success than the exact form of operation which is selected.

The answer to the second question proposed to us—the effect of operations for ptosis in neurasthenics on the neurasthenia itself—seems to me to depend, first, on a definition, and, second, on another etiologic point.

The term "neurasthenia" is, like the term "rheumatism," one which covers so many different states as to have no satisfactory meaning in modern medicine. The mere definition of this term has in fact provoked in the last ten years a large neurologic literature of its own. It is therefore all important that any discussion on this subject should start with a definition of what is to be talked about.

I take it that as surgeons we are not concerned with the subtleties of neurologic classifications and that in using this loose and popular term we understand merely a state of low resistance to the depressing influences of the environment, irrespective of the cause to which this low resistance may be due. If this is what we mean, it follows as a logical necessity that our operations will improve the neurasthenic state in those cases in which the lessened resistance is due to the lesions on which we operate, and in no others. An attempt to relieve neurasthenia of psychologic origin by surgical operations on local lesions will invariably make the abnormal psychologic state worse. Self-evident as this may appear, it is a general principle which is too often forgotten.

From a practical standpoint it has seemed to me that the crucial test of whether the state of lessened resistance which we call neurasthenia is, or is not, dependent on the effects of local lesions lies in a careful study of the chronologic relations between the local and general symptomatology. If the neurasthenia has been pronounced and prolonged before local suffering appeared the patients will seldom be benefited by operation. If, however, prolonged suffering of local origin has preceded the advent of the neurasthenia, complete relief of the local suffering will usually result in general systemic improvement, and in increased power of resistance to the general wear and tear of life.

Two general principles must, however, be always borne in mind: First, even in these cases the only way in which the operation can benefit the neurasthenia itself is by resulting in a permanent relief of local suffering; for this reason no operation should be undertaken until the surgeon has convinced himself by close study that the local suffering is directly dependent on the local lesion and will be relieved by its repair. Second, in neurasthenics an operation which does not definitely and permanently relieve the local symptoms invariably increases the neurasthenia.

It must be remembered also that in all those cases with which we as surgeons can properly deal, the state of lessened resistance to the wear and tear of life which we call neurasthenia is always the product of an excess of physiologic expenditure over and above physiologic income, and that even if this excess of expenditure be in part the result of local suffering, we can expect no satisfactory result from operation in patients who are so situated that their expenditure under the ordinary fatigue of life is, and must remain, in excess of their powers. In such cases the results of operation will be unsatisfactory unless the conditions of the patient's life can be so far altered that the vital expenditure after operation will be less than the patient's intrinsic vital income. I believe, then, that the attainment of satisfactory end effects on the neurasthenic state itself depends, first and primarily, on the selection for operation of cases in which the neurasthenia is the result of local suffering due to local lesions, and the exclusion from operation of all other cases; secondly, on the termination of local suffering by successful end results in the operation itself, and, thirdly, on successful regulation of the patient's life after operation, either by the surgeon himself or by an intelligent medical attendant.

The too frequent failures which we have all seen are usually the result of operating in the wrong cases; and, on the other hand, much injustice is undoubtedly done to many individuals who are subjected to what is generally regarded as the reproof of nervous invalidism when in reality their suffering is real, and derived from some remediable localized cause. Were we sufficiently wise in our selection of cases there would be few more satisfactory end results than those which we should attain in the treatment of the neurasthenic state itself by operation.

321 Dartmouth Street.

RELATION OF RECRUITING TO PREVENTIVE MEDICINE *

W. H. RENNIE, M.D.
WASHINGTON, D. C.

That old and trite saying that "the efficiency of an army or navy depends on the soundness of the health of the individuals composing it," was equally true in the past as in the present, when the study of preventive medicine is so much to the fore. To-day there is a deeper appreciation of the reality of this fact, and consequently the work of recruiting has assumed the serious rôle to which it is entitled.

"Since the most important factor in the efficiency of an army is its health, it follows that everything which may influence this in any way for the better or worse should be looked after with the utmost care. The men who compose an army are drawn from civil life, in which each individual has, to a greater or lesser extent, independent control of his time, choice of occupation, selection of food and dwelling-place, and general sanitary care. After enlistment, soldiers lose most of this independence; they are housed, clothed, fed and exercised under regulations which it is beyond their power to amend; they are moved from one point to another, differing perhaps very widely in climatic and other conditions, under orders which they may not presume to question; their hours for sleep, meals, work, and recreation are fixed for them without consultation with them, and without regard to individual or communal preference."[1] This applies with equal force to men-o'war's men.

The importance of the work of recruiting is more particularly emphasized when one considers the large percentage of rejections, 67 per cent., the few accepted, 33 per cent.; and of the latter, despite rules and regulations and utmost care, some must be discharged on the first re-examination on the receiving ship, the number surveyed each year not in the line of duty or existed prior to enlistment, besides the cost in time, labor and keep, loss to the government, and the hard fact that the physically undesirable recruit is filling the place otherwise occupied by a good man.

The life at sea is at times arduous, calling for stamina and unexpected demands at any hour of the day or night, for the man enlists for general service, for war as well as for peace, never forgetting that the question of the line of duty and pension may arise in each case.

The applicant, as he presents himself at the recruiting office, is not of a distinct and separate class; on the contrary, he represents all types and comes from all walks of life, from the highest to the lowest. He is the graduate in medicine, law, theology, the teacher, the pharmacist, the student, the actor, the artisan, the clerk, the laborer, the schoolboy, the gentleman hobo and the tramp; from nearly every field of human activity men seek entrance into the enlisted force of the United States Navy.

Among such a collection of potential men-o'-war's men are met all degrees of physical defects as well as physical perfection (so far as this is possible); all degrees of cleanliness of person and clothes; men with and without means of livelihood; the stupid and the mentally weak, ascending to the highly trained and educated; men of travel, men from home and the poor devils looking for a home, men of the city and men off the farm; those of unsavory reputation, the lovelorn and other runaways—in fact, there are no exceptions, for all classes of men, for all reasons, wend their way to the examining room of the recruiting office.

The vagrants, the great unwashed, are undesirable as a class; they bathe at long and irregular intervals; their habits morally, mentally and physically, are scarcely commendable, and they have learned to dislike work. Sometimes I think they should be excluded without exception; the price paid for the few good men is too exorbitant for the undesirables sure to gain entrance. Just as the chain is no stronger than its weakest link, so the man when needed will break at his weak point. The ounce of prevention is also valuable in the work of recruiting.

In all wars the number of deaths from disease has been far in excess of that of casualties, and more discharges are due to sickness than to injuries.

"The examination is very thorough, and includes the mental condition, the principal organs of the body, the general formation, the chest capacity, the condition of the teeth, skin, joints and feet, and the presence or absence of hernia, varicocele and other disqualifications."[2] The recruit must be well-built all around, superior to the average in muscular development, or, if in youth, have potential strength. He must be sound, ready for all kinds of work and sudden strain.

2. Practical Hygiene, p. 572

It must always be remembered that the man on the sick-list is counted on the ship's complement of enlisted force, and that his station would otherwise be filled by a capable man. "Such men are not merely ineffective themselves, but exercise a detrimental effect on the morale of their associates. The mental attitude of a man whose physical infirmities prevent him from fully meeting the demands of his station and surroundings soon becomes one of chronic discontent and discouragement, a nuisance to himself, his shipmates and his superior officers."[3] A man, attempting to enter the navy conceals and makes light of any trouble, but once enlisted, the same man magnifies it. A man-o'-war's man can not be coerced when the question of an operation arises and hence, he will often seek his discharge on the slightest provocation. "Certain disease influences are prevalent in, and more or less peculiar to, certain parts of the country, and applicants for enlistment from these sections represent the possibility of being the victims of them in such form and stage of development as would escape detection by the usual routine examination unless specially looked for."[3] Such, for instance, are the apparent heart affections of altitudes like Denver.

"The examining surgeon shall consider carefully the adaptability of the applicant in relation to the character of the duties which he may be called on to perform. Moderate height and compact build are requisite in the rating of fireman and coal-passer. The duties pertaining to these ratings are extremely arduous, and applicants for such positions must conform in every particular to the required physical standard."[4] The examining surgeon should remember that all candidates examined for the several special ratings are enlisted for the performance of all duties pertaining to the naval service, ashore and afloat.

The city-born and bred are already inured to certain hardships and to all diseases of children. Dr. Woodhull, lieutenant-colonel, Medical Department, United States Army, however, says on this point: "In raising new troops, when it is possible to select, for sharp and immediate active service take town-bred men. If a year or two can be added in which to train them, take country-bred men. Open-air military life is physical promotion to city men accustomed to irregular hours, unwholesome meals, and poorly ventilated rooms. To country lads the irregular and sometimes scanty meals, broken rest, necessity for prompt and exact action, and above all the certainty of acquiring such diseases as measles, whooping-cough, and mumps, which town boys always have in childhood, are very exhausting. After a year's training, country youths are more valuable."[1]

The recruit must be sufficiently young and moldable in order to adapt himself to the new life on board ship which, at the best, is unnatural. The age for entrance must be between 17 and 35.[1]

"It is almost the universal opinion that recruits ought not to be accepted below 20, or better, 22. At 18 years, the recruit is immature; the bones are not fully formed, nor have they reached their final hardness; the epiphyses have not become incorporated with the shafts of the long bones; the joints are not fully developed; the chest has by no means attained its full capacity; and the organs of the body, in general, are immature. So it happens that, at this age, it is useless to expect him to be in good condition after long-continued exertion, or to undergo privations which are nothing to the man of mature years and strength. At this period of life, he is still in the growing stage and needs all the energy of his body to bring the organism to completion, and the influences which mature soldiers contend against with varying degrees of success, namely, vicissitudes of weather, long marches, hard work in trenches, possible overcrowding in barracks and camps, poor ventilation, and poor and insufficient food, send him very quickly to the hospital."[1]

"Taken between the ages of 18 and 20, and drilled and trained with due regard to his immaturity and limit of endurance, the recruit often shows great progress in general development within the first year, particularly if, before enlistment, he was poorly fed, clothed, and housed, and engaged in an indoor occupation. His work should be moderate in the beginning and only gradually increased, since changes for the better in the human body can not be brought about suddenly like those for the worse, induced by attempting to do too much at the outset. Since his lungs, heart, and blood-vessels are not yet fully developed, he can neither go through the manual nor cover ground like a seasoned soldier. The heart is called on by the new and unaccustomed exercise to contract at a greater rate than had been its habit and the recruit soon becomes 'winded.'"[1]

While it has been the experience that men below 20 or 22 are too immature physically to make good soldiers, this does not hold good in the case of sailors, whose training and work do begin in accordance with his strength, and is gradually increased in demands on the newly added growth; this training occurs under the most hygienic surroundings. The life on board ship and at sea is one filled with novelties, and an open-air existence and the duties incident to this life might well be compared to a course in physical culture, whereby there is obtained a broadening of the shoulders, deepening and expanding of the chest, and a general symmetrical rounding out of the muscular frame. The change in the first year is remarkable; natural growth can claim but a portion of this rapid development.

One must not lose sight of the fact that after enlistment the recruit receives the same watchful care as a new-born babe, or blooded animal. His bathing-hours are prescribed, his clothes selected for him and their cleanliness assured by frequent careful inspections, and his food, likewise, is provided with the same care and regularity.

Men over 35 may reenlist, and more leniency for minor defects is exercised. "An enlisted man, not under treatment, but with infirmities contracted in the line of duty, not such as to prevent his performing the duties of a soldier, may be reenlisted, since it is recognized that what he may lack in some minor particulars in soundness may be counterbalanced by experience and habits of discipline."[1]

The examination is of necessity searching, since disability not only interferes with the best work, but there is in some cases the danger of carrying contagion to others. Every recruit is immediately vaccinated, and kept in the detention camp three weeks before he is permitted to come in contact with the other men. Every deviation from the normal must be noted for a final estimate, or summing up, in accordance with the navy standard.

In the British army defective development causes the greatest number of rejections, then defective vision, and third, diseases of the circulation. For the last quarter here in St. Louis, out of 689 applicants, 169, or 23 per cent. were accepted. Of these 689, 140 or 20 per cent. failed because of poor physique (underweight). The following rule is followed: Up to 5 feet 7 inches the weight should be twice the height or 2 pounds to the inch, and for every additional inch 7 pounds more in weight must be added. The chest measurement is a little less than one-half the height. The biggest men are the most deceptive in appearance, and can not be depended on for endurance: far from it. Men of the laboring class are often properly proud of their muscular development, and with great self-assurance undergo the physical examination, in many cases only to be bitterly and perplexedly disappointed.

---

[3] Report of Surgeon-General, United States Navy, 1909.

[4] Instructions for Medical Officers, U. S. Navy, 1909.

Of the 689 applicants 102 or 14 per cent. failed because of defective vision.

"No applicant should be recommended as qualified for the rating of gun-pointer who can not read with the right (or aiming) eye at 20 feet the line on Snellen's test-card, which is normally seen at 15 feet (i. e., 20/15 vision). The minimum of 20/20 vision should be required with the eye not used in aiming. The test-card should be well illuminated."[4]

It is astounding how great is the amount of ignorance due to faulty eye-sight alone. Some men attempt to read the test-card twice with the same eye or to memorize the letters; one applicant with 3/20 vision in each eye had never worn glasses. Of the 689 applicants 13 per cent. were rejected for flat-foot, 6.5 per cent for heart affections, 5.5 per cent for defective teeth, and 4.5 for color-blindness.

For Asiatics, enlisted as mess attendants, the bars must be lowered from the American standard of physique to one corresponding with the former race, though one should always be on guard against such diseases as plague and beriberi. The Filipino is of smaller stature and the requirements are that young men of 18 to 19 years of age must weigh 105 pounds (15 pounds lighter than the American average) and have an expansion of 2 inches; those men of 21 years of age must be 62½ inches in height, must weigh 110 pounds and have a chest mobility of 2½ inches, in sharp contrast to the American of the same age, who must weigh 18 to 20 pounds more.

Men for the hospital corps must be superior to the average applicant; a grammar-school education is required for the men intended to perform a special and responsible work, to assist the surgeons in his varied duties, acting as his first assistant or anesthetist during major operations; in fact, their duties correspond to those of the male trained nurse of our professional brethren practicing ashore. To make assurance doubly sure, the recruit must sign a clean bill of health: "I believe myself to be physically qualified to perform the duties of the rating in which I may be enlisted." Likewise, the examining surgeon certifies that "I have carefully examined, agreeably to the regulations of the Navy, the above-named recruit, and find that, in my opinion, he is free from all bodily defects and mental infirmity which would in any way disqualify him from performing the duties of his ratings, and that he has stated to me that he has no disease concealed or likely to be inherited."

The one essential requirement for the best results in recruiting is the strict adherence to a fixed, invariable, systematic routine method of examination.

The medical officer must possess the proper spirit for recruiting to secure men physically good; he must exercise good judgment in the case of men on the borderline, never forgetting the important reasons for giving the government the benefit of all doubt, being very careful to note all minor defects which do not necessitate the rejection of the applicant. All kinds of influence are brought to bear on the judgment of the examining surgeon, aside from the question of competition of the recruiting officers to make a record in number rather than the standard of recruits of those enlisted. Physicians in civil practice, as well as politicians at times make it very emphatic how desirable it is to the government to obtain the services of their sons or friends.

The opposite state of affairs is illustrated by a pathetic though rather amusing instance: A young man of 21 desired to enlist while we were at Savannah, Ga. The mother called on board and, with a distressing flow of tears, asked how her son could be enlisted when the family physician sent word that he was physically incapacitated. There being no defects, the boy was qualified physically, much to his own delight. The father came on board with a gun to compel, in this gentle way, the non-acceptance of his son. The boy decided to run away from his family and of his own volition, being of age, joined his chums at the railroad station. We sailed down the coast and up the Mississippi river as far as Cairo, Ill., making numerous stops for the purpose of recruiting, and in the course of about four months we returned to Savannah, Ga. Meantime the young man had sent home photographs and graphic accounts of the fascinating life of the training station. The first day in port the mother came on board and, with similar tears, begged us to enlist her younger son, who, by the irony of fate, failed to pass the physical examination.

It has been demonstrated repeatedly that physicians ashore do not obtain the best results in recruiting, simply because they have not had the peculiar training which is acquired only under actual service conditions.

After this brief review of some of the more salient features of the subject of recruiting for entrance into the United States Navy, I believe that all will agree with me that good powers of observation, a keen eye, mental alertness, considerable knowledge of human nature, complete understanding as to service conditions and the calls that are made in each rating, besides a proper interest for the service are prerequisites in the medical officer who is detailed for the recruiting office, where, by far, the major part in the way of preventive medicine is accomplished for the navy.

Yaws Transmitted by a Fly.—Dr. E. W. Gudger (*Science*, Nov. 4. 1910) calls attention to an old recorded observation that yaws is transmitted by a fly. The traveller, Henry Koster, in his account of travels in Brazil (1809-1815), gives a description of the disease, yaws, in which he says: "This horrible disorder is contracted by inhabiting the same room with the patient, and by inoculation; this is effected by means of a small fly, from which every precaution is oftentimes of no avail. Great numbers of the insects of this species appear in the morning, but they are not so much seen when the sun is powerful. If one of them chances to settle on the corner of the eye or mouth, or on the most trifling scratch, it is enough to inoculate the bobas, if the insect comes from a person who labors under the disease." In commenting on this Gudger says that it will be noted that, while Koster is not able to give the specific name of the fly, he definitely declares it to be a certain fly with well-marked characters. It may be well to add that the disease called "bobas" throughout Brazil, is identified by Koster himself as identical with the "yaws" prevalent in Venezuela and the Guianas.

THE CONSERVATIVE UTILIZATION OF THE WASSERMANN REACTION

D. M. KAPLAN, M.D.
Director of Laboratory, Neurological Institute, New York; Serologist to the Montefiore Home
NEW YORK

The statements in this communication are based on a study of over 3,200 reactions, and in view of the confusion and uncertainty that still prevail in the minds of many physicians as to the significance and value of the Wassermann test I am hopeful that this work will tend to render clear some obscure points and enable us to handle the question of syphilis from a serologic point of view with greater accuracy than heretofore. The impression that I have received from almost two years' work with this reaction and the benefits that physicians and patients derive from its application is that the value of the Wassermann test for diagnosis and therapy has been greatly overrated. It still remains an interesting problem for the biologists to solve, but so far their work has not been decisive enough as to enable the practicing physician to rely implicitly on the outcome of a Wassermann test. I do not wish to discredit the work of Bordet and Gengou, nor is it my intention to belittle the application of the phenomenon of complement deviation to the diagnosis of syphilis. I do, however, maintain that the promiscuous use of the test by insufficiently instructed physicians is as dangerous as the use of reports from tyro serodiagnosticians. I lay particular stress on this point, because such use to my knowledge has been the cause of serious damage. The accompanying tables containing the material gathered during twenty months of work with the Wassermann test owe their scope and variety to the kind assistance of Dr. Abrahamson and the staff of physicians at the Montefiore Home. Its completion and the study of the effects of mercury on tabes was accomplished at the Neurological Institute, whose medical officers were ever ready to furnish necessary data for this work.

CONSIDERATION OF TABLES

The first and largest group of cases analyzed was composed of cases of locomotor ataxia. The Wassermann reaction in this disease, contrary to the still prevalent conception that all tabetics are syphilitic, was positive in 88 per cent. in one group of cases and 44 per cent. in another group. In considering tabes dorsalis one must not lose sight of the patient's condition, whether in the active tabetic state or in the quiescent. The physician's disappointment is quite evident when a negative Wassermann is reported on a patient with tabes; it is the conviction of many physicians that every tabetic ought to give a positive reaction, as they believe syphilis to be the only etiologic factor concerned in this disease. The tables show that over 300 cases of tabes dorsalis were analyzed and on an average only 66 per cent. of cases gave a positive outcome. Whatever the substance may be that is responsible for a positive Wassermann reaction in a patient with tabes, it may be taken as a sign first, that his tabes is of syphilitic origin, and secondly that if active manifestations are present mercury is indicated. The contention makes it quite evident that the knowledge of the tabetic manifestations is very essential to successful therapy. Whenever a serum is analyzed from a case of active tabes (crises, girdle, shooting pains) the reaction is usually positive (88 per cent.). This sig-

* Of 540 cases analyzed for diagnosis, unmistakably positive findings were obtained in 80 per cent. Weakly positive reactions were obtained 8 times in cases which most likely were not luetic; 6 of the patients had jaundice.
† The 2 positive cases improved with iodids.

nifies that the disease is most likely of a luetic etiology and that mercury will not injure the patient. In case the reaction is negative in a patient with active manifestations it is safer not to use mercury, as in such a case the cause of the tabes is likely not syphilis. In patients with straightforward tabetic signs without active manifestations the reaction is positive in only 44 per cent., as I found, and antisyphilitic therapy is as a rule of no avail. It is quite evident that the ataxia and other symptoms the result of the degenerative process can not be influenced by drugs. It is consequently a better policy to leave the patient alone even if the Wassermann reaction is positive, provided he is in a state of comparative comfort.

I have examined fifty-one serums from active tabetics and found the reaction positive in forty-four, *i. e.,* 88 per cent. It is my belief that this form of exudative tabes is due to syphilis when the reaction is positive and that in about 12 per cent. of active tabetics the etiologic factor in case of a negative Wassermann still remains an open question. As the etiology of tabes is an important factor from a therapeutic and sociologic point of view, it is to the credit of the Wassermann test, which materially enhanced our knowledge in this direction and brought us considerably nearer to the truth than we were before the era of serodiagnosis in syphilis.

The results of my work support the old contention of von Leyden, who is against the idea that all tabetics are infected with syphilis, and tend to disprove the teachings of Erb, who believes that they are all of luetic origin. The administration of mercury in any of its forms in the case of an active tabetic should always be preceded by a careful Wassermann reaction and the drug used only when the result is positive.

It came to the notice of Dr. Joseph Fraenkel that some forms of tabes were decidedly harmed by mercury and that the course of the disease was markedly aggravated. I was enabled to follow this experience with the Wassermann reaction and found that in patients with the active form of the disease with a negative reaction mercury did no good and in some cases harm. It has been clinically observed that the Duchenne form of tabes is made decidedly worse by the use of mercury. I may therefore say with justice that if a clinically undoubted active tabes gives a negative Wassermann reaction, it may be taken, in view of what has been said before, as better to abstain from antiluetic treatment. Furthermore, the Wassermann test intelligently used will help us to solve more definitely the differentiation between the real tabes and the genuine general paresis of the old type, from the so-called pseudotabes and pseudoparesis and the so-called mixed forms, placing them all under one category of syphilis of the cerebrospinal system. Applied to therapy, the Wassermann test points out the indication for or against the use of mercury in the exudative types and the advisability of treating degenerative tabes is left to the clinician. As a rule the uselessness of mercury in these cases is conceded and the irreparability of the diseased tissues is accepted.

THE WASSERMANN REACTION AND HG IN TABES

Active Exudative Tabes.—Reaction positive, Hg indicated. Reaction negative, Hg contra-indicated.

Quiescent Degenerative Tabes.—Positive or negative there is very little that Hg can do to restore function.

To come to the conclusion as to the etiology of a case from the therapeutic efficiency of mercury is also erroneous. In the case of tabes we know that improvement may follow any and no treatment. It is advisable not to form an opinion as to the etiology of a disease from the accepted therapeutic specificity of a drug like mercury.

A patient in the Montefiore Home with all the signs of a brain tumor was treated by Dr. Fraenkel some fifteen years ago. The mercury apparently did some good and the etiology at that time was uncontrovertibly established. After three years of rather good health the patient succumbed to a relapse of the previous condition and at the autopsy showed a sarcoma from the thalamus to the fourth ventricle.

Another case (from the service of Dr. Spiller, to whom I am very thankful for this fact) showed a positive Wassermann reaction from a very competent worker. In this case also the patient was suffering from a brain tumor. The reaction was the occasion of vigorous mercury treatment which did no good whatsoever. After a short time the patient died and the autopsy in this case revealed a gliosarcoma of the brain and on abdominal examination a gumma of the liver. This warns one not to be too much dependent on laboratory reports and never to permit one's clinical acumen to be eclipsed, no matter how trustworthy the laboratory worker. In the above case it may have been of vital importance to have an operation performed if the possibility of a dual cause were recognized; mercury was given the preference as a result of the Wassermann reaction. This experience teaches a lesson: never to allow the Wassermann test to decide for or against an operation.

In general paresis mercury is as useless as in degenerative tabes. The poison that brings about the changes in the nervous system is very often stimulated to increased energy by the administration of mercury. I know of two instances in which the patients were reduced to invalidism, although previous to the use of mercury their vegetable organs were in a perfect condition. Two months after the use of the drug the patients died. In both the reaction was positive. The surprising therapeutic results with mercury in general paresis and the reported cures need closer investigation. There are very few distinctions between some cases of general paresis and some forms of syphilis of the brain and spinal cord. It is not at all too far-fetched to consider these improvements and cures as having been effected on patients suffering from syphilis of the brain and cord. The Wassermann reaction in these cases does not shed any light on the condition although the Munich school claims to be able to differentiate between the two clinical states. The only distinction that Plaut says can be found in the cerebrospinal fluid when a Wassermann test is performed, is that the reaction is always negative in syphilis of the brain and cord, and positive in general paresis.

Among the fifteen cases of pseudohypertrophic muscular dystrophy of various types all reacting negatively, the parents were examined in two instances, also giving a negative result.

It is of interest to note the positive results obtained in scleroderma. The fact that the reaction was positive does not in the least establish the etiology of this skin condition. It is personally known to me that mercury used for a long time in no way influenced the course of the disease.

The large percentage of positive results (75 per cent.) in aortic aneurisms greatly reflects on the cause of this disease. The predilection of involving blood-vessels is a well-known peculiarity of the syphilitic incitor, and the improvement that follows the timely administration of mercury in some cases tends to confirm the etiology in many instances.

In pulmonary affections the presence of the tubercle bacillus decides the etiology. I examined 280 cases and found the reaction six times positive. Two patients at no time showed the tubercle bacillus, and improved after mercury; two others also showed the presence of the bacillus; of these one improved and one died. An autopsy showed tubercles and a gumma in the lung and endarteritis luetica of the larger blood-vessels, especially the aorta. The cases of gastric subacidity gave a positive outcome in ten serums. These patients showed an increase in acid values after mercury. The positive Wassermann reaction need not introduce the idea that lues was the cause for the subacidity. I wish to thank Dr. W. G. Lyle for pointing out to me these facts, who at the time when these tests were made did not wish to express an opinion as to the significance of the coincidence. In a few cases a history of lues was obtained.

I encountered four cases of arthritis deformans with positive reactions; one of these improved after mercury administration; the course of the other three is unknown to me.

I shall now endeavor to form a conclusion as to the value of a negative Wassermann obtained from a study of the behavior of the test in patients with primary lesions and patients with symptoms bordering on this period.

THE VALUE OF A NEGATIVE WASSERMANN TEST

The table shows the percentage of positive reactions in primary lesions and in cases bordering on this period to be rather large. It is this class of patients that furnishes the greatest number of positive results. A negative outcome in a patient showing a primary lesion, or clinical signs suggestive of the symptoms of the stage bordering on the ulcus durum period ought to put the physician on guard as to the true etiology of the symptoms. A negative reaction during this period carries great weight, as the reaction is usually strongest during this period, and with even little technical knowledge usually gives a strong positive result. Comparing the chances of error from a clinical and serologic point of view it seems to me that it is much easier to err clinically than serologically, of course bearing in mind the stage of the disease. I would suggest that in such a case in which the reaction is negative, in view of the above symptoms, whenever the patient's condition permits it the physician should pursue the orthodox method of waiting until more evidence for or against syphilis appears. This is especially recommended in dermatologic practice, bearing in mind at the same time that waiting gives the spirochetes a firmer hold on the patient's constitution. I also believe that it is less harmful to let the patient wait than to subject him at once on meager evidence to the influence of mercury and have him ever afterward carry the odious knowledge of having been treated for syphilis. There are many such patients who years later consult a physician for unimportant ailments and when the possibility of syphilis is inquired into as a matter of routine their experience of the past gives a dominating impression and potassium iodid is prescribed. There are many such cases unjustly stamped luetic. The practice of waiting for corroborative evidence is a useful one because, first, we will not treat an innocent lesion for syphilis, and secondly, we may be able better to judge the value of Wassermann reactions. The experiences with Wassermann test brought me fourteen such patients. All of these were told to wait. In six cases undoubted signs of syphilis developed; the remaining eight at no time showed any symptoms suggestive of specific disease, in spite of the fact that no specific treatment was carried out. It is therefore my conviction that, whenever under the above circumstances it is possible to wait without placing in jeopardy the patient's health, this delay should be employed.

There is no test at hand to-day, no matter how carefully performed, that will infallibly demonstrate the true state of affairs and especially with such a treacherous disease as syphilis. Since the introduction of the Wassermann test many patients come to the serodiagnostician to ascertain if the disease is out of their system. They admit that long ago they had an eruption or a sore and were placed on mercury. The physician wishes to ascertain the efficiency of his treatment. As a rule most of these patients react negatively; first, because not sufficient time has elapsed since the last administration of mercury, which tends to negative the reaction; secondly if sufficient time did elapse, it may not be at all impossible that the lesion or eruption was not specific. In the absence of any help beside one's clinical training, before the days of the Wassermann reaction, it was very easy to make a mistake. It is gratifying to know that to-day, thanks to the Wassermann test, very few innocent lesions are submitted to antiluetic treatment and restrictions, and only those are obliged to carry the knowledge of having syphilis who were really infected.

SYPHILOPHOBES

There are some patients who take up the physician's time with unfounded fears as to the condition of their blood. Such patients are in great fear of having had remotely a syphilitic infection. A few come with ready-made diagnoses and bring in evidence the statements of a physician who told them they had the disease. If such a patient presents clinically no signs of syphilis, in any of its stages, and if this present opinion issues from a syphilologist, the reassurance to the patient is greatly enhanced when the report of the Wassermann reaction is negative. My point is carried if it is understood so far, that the diagnosis for or against syphilis clinically, and the negative or positive laboratory reports are of decisive significance only when used together.

As to the constancy of the Wassermann reaction in syphilis, the last word has not been said; as far as frequency and sharpness are concerned old leprosy cases present a much more definitely positive reaction than old syphilis. It is worthy of mention at this juncture that the older the leprosy the more marked the reaction, unlike the majority of cases of old lues. What there is in common between lues and leprosy is a speculative subject; the future may find the link that makes both diseases interfere with hemolysis while using the same inhibitory extract.

THE WASSERMANN REACTION AND ANTILUETIC THERAPY

If in a well-treated case of syphilis a previously positive reaction becomes negative, it is permissible to draw a favorable prognosis therefrom. It is certainly gratifying to note the disappearance of the Wassermann reaction, provided the clinical manifestations go hand in hand. A negative Wassermann in a patient presenting clinically vestiges of lues is not to be considered conclusive. It is much more rational and useful to obtain a cure clinically first and to have the laboratory corroborate the cure with a serum reaction. In tertiary syphilis a negative reaction is of no value after treatment, except when the patient's serum is so negative that when added to another positive serum the combined mixture will result in a negative outcome. The test is performed as follows:

Five hundredths of a c.c. of an established positive luetic serum are placed in a test-tube and mixed with 0.2 c.c. of the negative luetic serum to be tested; the mixture is incubated for half an hour and complement added. This is incubated another hour, and cells and amboceptor added. Observations are then taken.

A somewhat analogous method was recently advocated by Brauer.[1] The author omits the study of the effects of the mercury serum (serum from patients without syphilis who received mercury injections) from normal individuals on luetic serums, a study to which I refer in a recent article.[2] The consideration of the Wassermann reaction from the therapeutic standpoint is not exhausted by the few examples cited. It must be borne in mind that some tertiary syphilitic manifestations can never be improved by antiluetic treatment and it must not necessarily follow that a luetic process is at a standstill because of a negative Wassermann reaction. I know of patients with tertiary syphilis in whom a negative reaction could never be obtained, no matter how thoroughly mercury was administered.

EFFICIENCY OF WORKERS

It is not to be denied that the Wassermann reactions reported on by beginners in insufficiently equipped laboratories certainly did some harm; even the best work from laboratories equipped for the sole purpose of performing the reaction loses much of its value when used promiscuously by physicians who look for too much help from such reports. I know of instances in which negative reports decided the etiology of a disease without further clinical investigation. Such confidence is met rarely to-day, as physicians begin to appreciate that even a positive Wassermann reaction does not always spell syphilis.

It becomes the duty of everyone actively engaged in the performance of the reaction to render clear certain shortcomings of the test and to place clearly before the physician who is to use the submitted report, the significance of a positive, a weakly positive and a negative reaction, and to what extent the test can be relied on as a whole. It is needless to emphasize that such advice should hail from matured workers only, who not only know how to perform the test, but whose enthusiasm has cooled as the result of an extensive experience. It is to be granted that the best workers make mistakes; some are pardonable, others not; but when we consider the delicate adjustments of the test, it is no wonder that different serologists report differently on the same serum. The clinicians as a rule, in the case of conflicting evidence, form their own opinion and treat the condition on its merits.

A negative report on a ripe syphilitic serum, however, does reflect on the abilities of the serologist (considering the difficulties of the reaction) as well as positive report on a serum from a healthy person. It is important to bear in mind that the value of a negative Wassermann reaction for diagnosis, except in the instances mentioned before, is almost *nil;* it is different when the report is requested to ascertain the therapeutic efficiency of a treatment. The patient's well-being and the time elapsed since the last use of the drug must be noted. There is generally an error committed in sending patients to the laboratory without stating the time elapsed since the last treatment. A negative Wassermann reaction together with a complete absence of subjective and objective symptoms, with treatment as remote as possible (six months or more) is the ultimum bonum the clinician desires to attain.

The instructions to such patients are to have them report at stated intervals for a physical examination in order that the least deviation from the normal may be investigated with the help of a Wassermann reaction. Discharged patients should be systematically supervised with the help of the laboratory; the reactions should be kept on record, and the patients giving persistently negative results may be considered as practically cured. Such patients may even be permitted to marry. Some physicians use the Wassermann test for therapy only and depend very little on its help for diagnosis. In many instances the test is performed with the sole intention of reassuring the patient.

READING AND REPORTING RESULTS

It is very sad but nevertheless true that our knowledge of the reaction has not progressed far enough to make all work on these lines uniform in all laboratories. In fact, the same serum if sent to a number of laboratories will result in as many different interpretations. These conflicting reports fundamentally shake the confidence of the clinicians who are to use them.

There is a movement on foot in New York to bring together practical serologists and render their methods for work and standardization more uniform than heretofore. Such endeavor, I believe, will bring about more accurate work and less conflicting results. It may perfect the methods so that the physicians will be able to use it more extensively, especially for therapeutic purposes. It may also change the conception of the syphilitic etiology of some diseases; for instance, locomotor ataxia. For the present, I believe that the only way of rendering useful service to the cause of serodiagnosis is to employ in the case of the Wassermann test the original method plus another modification and to become thoroughly conversant with its peculiarities. To minimize chances of error it is best to perform the reaction twice with each method and to report results after the elimination of every reaction that is not unquestionably positive. I wish to emphasize particularly this manner of coming to conclusions and to disregard any form of reading results and reporting to the doctor in an unintelligible and confusing manner. I am referring to the attempt made by some workers to designate the results of their reactions as 80 per cent. or 90 per cent., etc. Citron had some such arrangements using a certain number of crosses (+ + +) and dashes (+ + —) or (+ — —) to impress on physicians the intensity or weakness of his results.

I wish to be placed on record as considering this form of arriving at conclusions quantitatively as absolutely unreliable, for the simple reason that, no matter how uniform the every-day work of a serologist, he will on many occasions report differently on the same serum. Irrespective of this, we are not at all advanced enough nor are our methods uniform enough to justify the adoption of such a meaningless scale for recording the results of Wassermann tests. While one will have 80 per cent. another will have 90 per cent. and a third something different again. I believe that the answer "positive" or "negative" for diagnostic purposes is all that our colleagues expect from us and that a confusing report of 80 per cent. positive, especially where a definite answer is expected, will tend only to mislead the physician. When the reaction is performed to ascertain the effect of treatment no patient should be discharged until the serum behaves like a normal serum. The serologists who wish to express their results numerically may be excused in the case of therapeutic tests, as physicians are sufficiently instructed in the majority of instances to know that only the entire disappearance of the reaction from the serum is of value in successful therapy.

---

[1] Brauer: München. med. Wchnschr., 1910, No. 17.

[2] Kaplan, D. M.: The Theoretical Consideration of the Wassermann Reaction and Its Practical Application, Jour. Am. Med. Sc., July, 1910.

The method of forming conclusions is an important qualification of every serologist and no one ought to consider himself thoroughly competent to work with serum unless this degree of perfection is attained. Luckily it is not so dangerous to make a negative report in a syphilitic individual as it is to make a positive report in an innocent patient. I therefore state again that it is proper to perform the reaction twice, using the original Wassermann test and, as I have been in the habit of doing, also a Noguchi test. These tests are best repeated on the following day and anything that is not distinctly positive ought not to be used for diagnosis. No dubious results ought to be reported. It is every time better and by far safer to admit that the result of the Wassermann reaction is inconclusive and that another reaction ought to be performed. In case the reaction is performed for therapy and the serum does not behave like an absolutely normal serum (negative) the patient ought to be treated more and have his serum reexamined after a suitable time has elapsed.

SUMMARY

1. When a serum is submitted for diagnosis the laboratory report should read "negative" or "positive." No qualifications as to degree are necessary.
2. For diagnostic and therapeutic purposes the laboratory report should always be collated with clinical findings.
3. Negative reports are of value in therapy.
4. Treatment should be stopped for four to six months after the patient becomes clinically and serologically normal and at the end of this period the test should be repeated.
5. All patients cured of syphilis ought to have for preventive purposes a test performed twice a year.
6. Any reappearance of the reaction even in traces is to be dealt with as under Paragraph 4.
7. Some patients who have had syphilis never lose the positive reaction in spite of any therapy.
8. A negative report obtained on a serum from a suspicious case should defer treatment until the course of the disease decides the etiology, provided there is no danger in delaying treatment.
9. With a positive report one must not lose sight of the possibility of another disease being present besides syphilis.
10. In my experience advanced scleroderma and old leprosy are more positive than old syphilis, quantitatively and qualitatively.
11. In active tabes 88 per cent. and in quiescent tabes 44 per cent. of positive reactions were obtained.

THE COLONOSCOPE

HEINRICH STERN, M.D.
NEW YORK

I have devised an instrument for the inspection of the sigmoid flexure which possesses a number of advantages over other instruments intended for the same purpose. The following description will prove this contention:

Figure 1 represents the sheath with obdurator. A is the sheath of ⅝ inch diameter and 12 inch working length. B is the obdurator, C the lamp. The wiring for the lamp is armored in the wall of the tube. The conduit projects neither on the inside nor on the outside of the sheath. The lamp itself is loaded in a capsule with a water-tight screwtop and a glass window. The capsule projects somewhat beyond the distal opening of the sheath, and is of material assistance in pushing aside rectal folds in the vicinity of the mouth of the sigmoid flexure, and may be utilized as a guide. The light arrangement is a novelty in all rectal examining devices. It permits the use of a telescope or optical system to see at right angles, thus enabling one to inspect the first and even the second portions of the flexure. D is an improved electric coupling with on and off switch; this coupling is very reliable. E is a stopcock, to which may be attached the air-inflating apparatus.

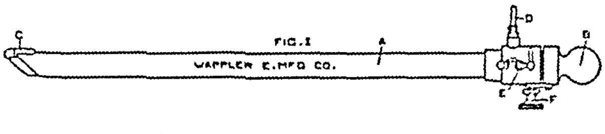

FIG. I

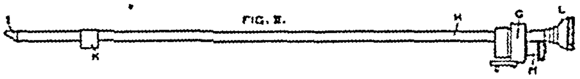

FIG. II.

FIG. III.

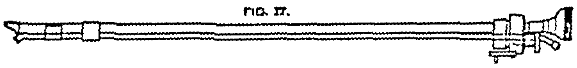

FIG. IV.

F is a locking and releasing device for the conical fittings of sheath and optical system. Its function is to lock and separate the sheath and its members while the instrument is in position without jarring, and to avoid discomfort to the patient.

Figure 2 is a double optical system: through the long tube one is enabled to see at right angles to the axis of the instrument, and through another eyepiece the portions in front are magnified, which facilitates their minute inspection. G is the cone fitting in sheath. H designates the telescope tube. I is the objective, giving a right sided and upright image. K shows a circular spring-holding tube, with lens system on one side of the tube. L is the eye-piece of the optical system, and M the eye-piece, which is removable and gives a magnified view of the parts straight ahead.

Figure 3 is a longitudinal section of the sheath, with an end for air-tight closing. It has a lens for bringing the object at the distal end of the tube nearer the operator's eye, and a rubber nipple admitting instruments for operation and application while the rectum and flexure are under air distention.

Figure 4 illustrates a lens system, with a tube bent on the far end for guiding and deflecting applicators into the flexure.

Military Versus Medical Heroes.—It is a curious commentary on our civilization of to-day that we litter every public place with granite tributes to brigadiers, while the families of these men [Reed, Carroll, Lazear and others] beat at the doors of Congress for adequate support and the crowd passes thoughtlessly by their graves.—Martin Cooley, *Jour. Outdoor Life*, October.

EXOPHTHALMOS IN BRAIN TUMOR

WITH REPORT OF EIGHT CASES [*]

T H WEISENBURG, M D
Professor of Clinical Neurology, Medico Chirurgical College,
Neurologist to the Philadelphia General Hospital
PHILADELPHIA

Little emphasis has been placed on the occurrence of exophthalmos in brain tumor if the literature on this subject is taken into consideration, and yet in the clinical description of such cases it is not infrequently mentioned My attention was particularly directed to this subject by a number of cases of brain tumor in which exophthalmos was a prominent symptom, and in a cursory examination of the histories of patients with brain tumor which I have observed during the last five years, protrusion of the eyeballs was present either unilaterally or bilaterally in ten, five with necropsy Of these, eight are here reported.

With the exception of isolated instances, the only extensive papers on the subject are by G Flateau,[1] and, to a less extent, by Rosenblath,[2] who together collected twenty-four cases of tumor accompanied by exophthalmos The neoplasms were located in practically every part of the cranial cavity Six were in the frontal lobe, two in the hypophysis, one in the pineal gland, one a basal tumor involving the pons, medulla and cerebellum, two in the cerebello-pontile angle, one in the pons, two in the cerebellum, two in the temporal lobe, one in the right lateral ventricle, and six were instances of internal hydrocephalus

The nature of the growths varied, consisting of glioma, sarcoma, neuroma, endothelioma, psammoma, and echinococcus, and it is evident from this that the character of the tumor probably had no direct bearing on the occurrence of exophthalmos any more than that certain forms of tumor may give metastasis

In some of these cases the orbits were examined, and in others the nature of the growths was such as to preclude the opinion that there was metastasis to the orbital cavity Exophthalmic goiter was excluded in all

The exophthalmos was bilateral in all the cases of internal hydrocephalus and in those tumors in which the lesion involved both sides of the brain, with the exception of one basal tumor In the unilateral growths the ocular protrusion was one-sided In all the protrusion was on the side of the lesion, with the exception of one cerebello-pontile tumor.

With the exception of the above no attempt is made to quote the cases from the literature Of my personal cases only a brief abstract of the histories is given

REPORT OF CASES

Case 1—*Gliomatous tumor of lateral and third ventricle compressing and implicating one optic thalamus with bilateral exophthalmos*—Previously reported[3] The patient was Miss M—n a girl about 20 who presented, as one of the early symptoms, a tendency to write in a perpendicular direction instead of horizontally, this being followed by gradual loss of vision Examination showed a marked bilateral choked disk The symptoms of intracranial pressure were very prominent When she was examined by me she had bulging of both eyeballs, with ptosis and deviation of the eyes in a downward direction, paralysis of associated ocular movement, and of convergence upward less to the right and left, and least downwards At necropsy there was found a tumor of the left lateral ventricle, which grew into the third through the foramen of Monro, and compressed the optic thalamus All the symptoms which she presented were readily explained with the exception of the exophthalmos

The tumor was a vascular glioma In the process of its growth from the lateral to the third ventricle it compressed the choroid plexus, the velum interpositum and the veins of Galen, and it is probable that it caused a stasis in the cavernous sinus, although unfortunately no orbital examination was made She had, however, a *congestion of the veins* in the eyelid, with edema and great pulsation of the vessels of the neck (Fig 1)

Case 2—*Tumor of the third ventricle, compressing both optic thalami with mild exophthalmos*—The patient, Miss C—s, was a girl of 17, who had marked pressure symptoms of brain tumor with choked disk of 5 diopters She had besides weakness of both external recti, paralysis of associated ocular movement upwards, with loss of convergence in the same direction, and a drunken, ataxic gait, with incoordination of the limbs At necropsy an extensive gliomatous tumor was found in the third ventricle, compressing both optic thalami and extending downward and bisecting the cerebral peduncles In this case the orbit was not examined, but there was no reason to suspect metastasis

Case 3—*Clinically diagnosed as tumor of the third ventricle with unilateral exophthalmos*—The history of this patient (Miss M——z) is very similar to that of Patient 2, but unfortunately no necropsy was permitted It was that of a girl of 27, who had choked disk of 6 diopters in the right eye and 4 in the left, with marked headache, nausea, vomiting, vertigo, temporary attacks of loss of vision, and a moderate prominence of the right eye Examination demonstrated weakness of associated ocular movement and of convergence upwards, and irregular nystagmus when attempting to look in the same direction, distinct cerebellar gait and incoordination, more marked on the left The symptoms were indicative of a possible tumor in the third ventricle, as they resembled very much the case cited above It is noticeable that the exophthalmos was on the side of the greater swelling of the optic nerve

Case 4—*Clinically diagnosed as tumor in the third ventricle Bilateral exophthalmos*—The patient, R——n, a boy of 12, had cerebrospinal purulent meningitis (?) from which he recovered Two months afterward he began to have headache, dizziness, nausea, vomiting, dimness of vision, weakness, and a staggering gait Examination showed paralysis of associated ocular movement upward and some impairment to the left, with disturbance of convergence in the same directions, weakness in the right face, arm and leg with Babinski reflex, and protrusion of both eyeballs, which was equally marked on both sides, and marked choked disk Unfortunately no necropsy was obtained

Case 5—*Clinically diagnosed as glioma of the pons and peduncle Bilateral exophthalmos*—The patient C——y was a boy of 14, who began with headache, nausea, vomiting, diplopia and difficulty in walking, which brought him to the Will's Eye Hospital, where it was found that he had a bilateral marked choked disk of 6 diopters Examination demonstrated bulging of both eyeballs, more of the right, with paralysis of associated ocular movement and of convergence upward and to the left, which later also involved associated movements to the right Besides, there was a distinct cerebellar gait, with weakness of the right arm and leg and peripheral weakness of the left seventh nerve The symptoms were indicative of a gliomatouh tumor in the upper part of the pons and peduncle, principally on the left side It was noticeable that the exophthalmos was greater on the right, although the symptoms were indicative of a greater tumor on the left

Case 6—*Glioma involving the posterior part of the medulla, pons and cerebral peduncle Unilateral exophthalmos*—This case has already been reported[4] The patient, R——y, was 44 years of age, and gradually developed general pressure and local symptoms of a right cerebellar tumor, with a choked disk of about 3 diopters. He was operated on over the right cerebellar area, but nothing was found. While before the operation there was only a partial weakness of the right third and of the sixth, some diminution of hearing in both ears and a little difficulty in articulation, after it there gradually developed a protrusion of the right eyeball and increased weakness in the distribution of the right third, and later paralysis of the right motor and sensory fifth, seventh and twelfth. Besides there was difficulty in articulation and swallowing. At necropsy, an extensive gliomatous tumor was found which involved practically all portions of the cerebellum, but especially the vermis in its inferior part and the left lateral lobe. It also extended diffusely into all the cerebellar peduncles, the posterior portions of the medulla almost as low down as the decussation, the posterior part of the pons and cerebral peduncles, and extended into the posterior portion of the left optic thalamus and internal capsule.

[4] Weisenburg T H Extensive Gliomatous Tumor Involving the Cerebellum and the Posterior Portions of the Medulla, Pons and Cerebral Peduncle and the Posterior Limb of One Internal Capsule The Journal A M A, Dec 18, 1909, p 2086

In this case the exophthalmos was unilateral, and on the side on which the cerebellar exploration was performed, and developed after the operation. It is to be noted that the symptoms of cranial nerve and cerebellar involvement gradually developed and became much more marked after the operation and coincidentally with the exophthalmos, and were explained by the growth of the tumor. There was no metastasis to the orbit.

Case 7.—*Basal tumor in posterior cranial fossa. Bilateral exophthalmos.*—The patient, Miss M——s, was a young woman of 20, whom I first saw in the Will's Eye Hospital and subsequently transferred to my wards in the Philadelphia General Hospital. She had all the pressure-symptoms of brain tumor, with marked choked disk, cerebellar gait, incoordination, central weakness of the right seventh, motor fifth and tongue, weakness of all the limbs, possibly more of the right, with increased reflexes. Very early she developed exophthalmos, more marked on the left, and there was besides immobility of the left eyeball with ptosis, the only movement possible being a slight movement downward and inward. The right eye could be moved downward, but not well in an upward direction. The patient died in the service of Dr. Spiller,[5] who found a very large tumor in the posterior cranial fossa. The occipital lobes had been pushed apart and the cerebellum displaced almost to a right angle with the brain stem.

Case 8.—*Sarcoma, compressing the temporal lobe, optic chiasm and posterior orbital bones. Unilateral exophthalmos.*—This patient, Mrs. S——a, whose case was reported a year ago by Dr. de Schweinitz before the Section on Ophthalmology, was a woman of 63, who, in 1900, injured the right orbit, but not very severely. Eight months afterward she began to have a bulging of the right eye, which from then on progressed. Dr. Wendell Reber studied her for a long time, and he states that there were never present ocular palsies. She had optic atrophy. The accessory sinuses were always normal. *X*-ray examination was negative. Eight years after the beginning of the exophthalmos, she was admitted to my wards in the Philadelphia Hospital, having then general epileptic convulsions, which were followed by temporary left hemiplegia. She never had any general symptoms of brain tumor. She died eight years after the beginning of the exophthalmos (Fig. 2).

At necropsy a tumor, a sarcoma, was found resting in the middle cranial fossa, it being about the size of a small orange. It compressed the orbital bones, the orbital surface of the temporal, the posterior part of the orbital surface of the frontal and the extreme anterior part of the cerebellar lobe. It also deviated and pressed on the optic chiasm, displacing it slightly to the opposite side, and also pressed on the foot of the cerebral peduncle (Fig. 3).

Dr. de Schweinitz, who was present at the autopsy, does not believe that the exophthalmos was the result of pressure on the cavernous sinus, although he cannot prove that it was not the result of this. He carefully dissected the specimen and there was no direct pressure on the sinus, nor was there on any of the nerves passing into the orbit. He says, however, that it is perfectly possible that the exophthalmos might have had such an origin. There was, he further states, a rather hard edema of the posterior tissues of the orbit.

In view of the autopsy, I do not know that it is possible to explain the exophthalmos in any other way than from a purely local cause, and the only local cause that can be given is pressure on the cavernous sinus, which possibility Dr. de Schweinitz himself admits. In support of this, the second, third, fourth and sixth nerves on this side were found diseased, this being especially true of the second, showing that pressure was exerted on it. Besides, the optic chiasm was compressed and deviated to the other side and the foot of the cerebral peduncle was distorted.

REMARKS

In a summary of my cases it is noticeable that in four, Cases 1, 2, 3 and 4, the diagnosis was tumor in the third ventricle, and in two, Cases 5 and 6, a glioma which involved both the pons and peduncle. In Case 7 the growth was in the posterior cranial fossa and was of such size that it compressed the occipital lobes, and twisted the cerebellum on its axis. In Case 8 there was a sarcoma in the anterior portion of the middle fossa which directly pressed on the orbit and the exophthalmos was undoubtedly the result of pressure on the cavernous sinus.

In all, the intracranial pressure was extreme, as indicated by the prominence of the headache, nausea, vomiting, vertigo and especially the choked disk. It is evident also that in the first six there was interference with the flow of the cerebrospinal fluid, inasmuch as there was either direct involvement of the third ventricle or pressure on the aqueduct of Sylvius.

The exophthalmos was bilateral in five and unilateral in three. In those in which it was unilateral either the lesion or the intracranial pressure was greater on the same side. In one, Case 3, there was supposedly a tumor in the third ventricle and the exophthalmos was present on the side of the greater swelling of the optic nerve. It is possible that protrusion of the left eyeball might have developed later. In the second, Case 6, the exophthalmos developed, after the exploratory operation, on the same side, and coincidentally with the development of other cranial symptoms. In the last, Case 8, the exophthalmos was the result of pressure of the tumor directly on the cavernous sinus.

In those in which the exophthalmos was bilateral the lesion was also bilateral and with the exception of one, Case 5, there was a greater prominence of the eyeball on the side of the greater involvement. The grade of the exophthalmos varied, it being marked in some and mild in others. In all it was progressive and came on early.

These observations agree with the collected cases quoted.

The conclusion, then, which can be drawn from the above is that exophthalmos occurs in brain tumor and especially in those cases in which there is great intracranial pressure and interference with the flow of the cerebrospinal fluid.

The question naturally arises how these factors produce exophthalmos. It is well known, especially through the physiologic studies of Leonard Hill, that the earliest manifestation of increase in intracranial pressure is engorgement of the venous circulation, this producing the familiar dilatation and tortuosity of the retinal vessels. There are, however, as has been mentioned by Cushing,[6] other external evidences equally characteristic, although less often commented on, which consist in dilatation of the vessels of the scalp and particularly the smaller venules of the eyelids.

[5] Spiller, William G.: A Further Contribution to Palliative Operations for Brain Tumor, The Journal A. M. A., Jan. 23, 1909, p. 277.

[6] *Osler's Modern Medicine, viii, 431.*

If in addition to the above there is exerted pressure on the cavernous sinus, thrombosis of which is the common cause of exophthalmos, the explanation is not at all difficult. Such was the fact in my cases, for in all there was direct pressure on the cavernous sinus. In the first four the tumor was in the third ventricle and pressure must have been exerted on the optic chiasm and basal sinuses, while in Cases 5 and 6 there was obstruction of the cerebrospinal fluid in the aqueduct of Sylvius, this undoubtedly causing dilatation of the third ventricle. In the last two there was direct pressure on the sinus by the tumor.

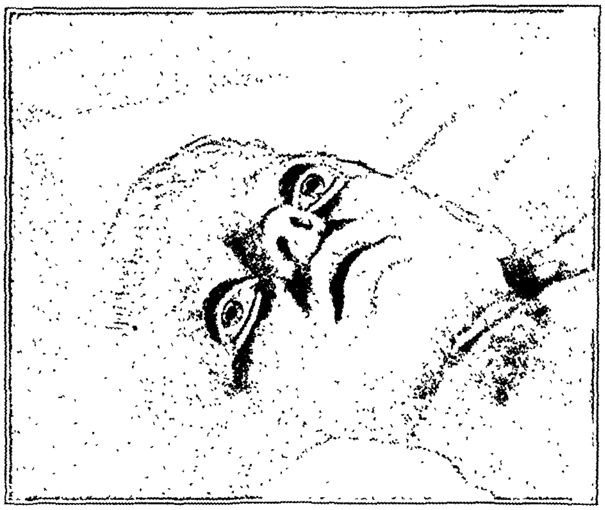

Fig. 1.—Exophthalmos in tumor of the third ventricle. Case 1.

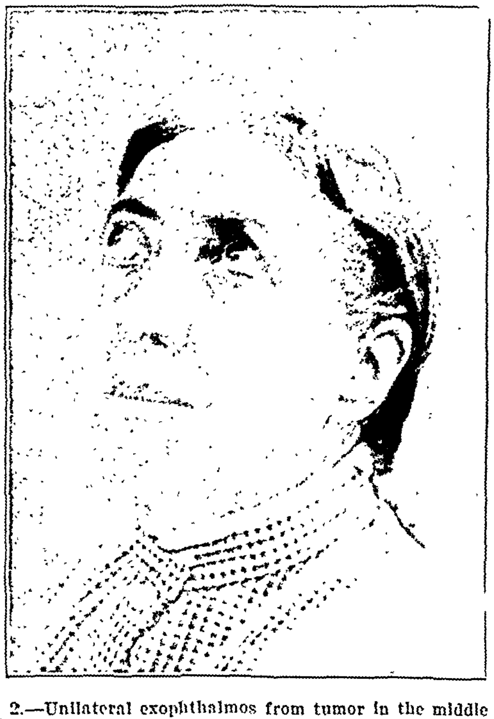

Fig. 2.—Unilateral exophthalmos from tumor in the middle fossa. Case 8.

Flateau advanced a very plausible theory for the occurrence of exophthalmos in those cases in which there is no direct pressure on the cavernous sinus. According to him the blood of the orbit under normal conditions is not depleted by the *facial vein* but by the *cavernous sinus*, and the outflow can be interrupted either directly by pressure on the ophthalmic vein or indirectly from a distant sinus; and tumors, for example, of the posterior cranial fossa can so obstruct the outflow of the blood in their own sinus that a portion must flow out by means of the cavernous sinus. Therefore, the back flow of the blood through the eye will be made so difficult that there will result a stasis in the orbit, this producing exophthalmos.

It is noteworthy, however, that in the material at my disposal, which consisted of the records of about 75 cases of brain tumor, exophthalmos occurred only in the cases mentioned and was readily explained by direct pressure on the cavernous sinus.

CONCLUSIONS

The conclusions which can be drawn from the study of this subject are:

1. Exophthalmos accompanies brain tumor more frequently than is generally supposed.

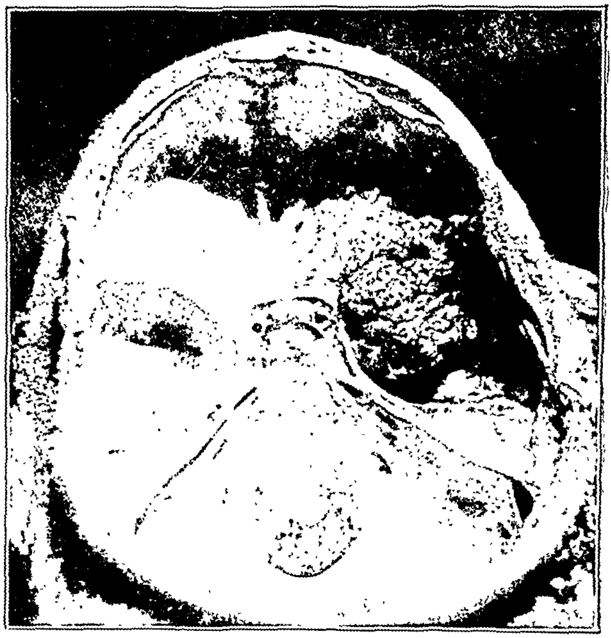

Fig. 3.—Tumor in middle fossa, producing unilateral exophthalmos. In patient whose photograph is shown in Fig. 2.

2. It occurs only in those cases in which there is great intracranial pressure, especially when there is in addition direct interference with the normal flow of the cerebrospinal fluid.

3. Exophthalmos is produced by direct pressure on the cavernous sinus.

4. Its presence is of some clinical value inasmuch as unilateral exophthalmos is nearly always indicative of an intracranial lesion on the same side.

5. In those cases in which the protrusion is bilateral there is nearly always a greater exophthalmos on the side of the greater intracranial pressure or lesion.

NEUROLOGIC REPORT BY DR. LANGDON

The case here reported presents no unusual features pertaining to the growth itself, its localization, the operative procedures or the recovery therefrom. In fact, it may fairly be classed as commonplace in those respects. It had been considered worthy of record, however, by reason of its peculiar symptom-complex, combining marked psychic as well as somatic disturbances; the practical absence of those important "general" symptoms; headache, vomiting, vertigo and papilledema; and the small amount of functional defect remaining at this date (March 16, 1910) four months after operation.

History.—Nov. 5, 1909, Dr. R. B. Hannah,[1] of Georgetown, Ohio, asked me to see a woman who had been developing some mental symptoms for a few weeks. It was also stated that preceding these evidences of insanity there had been some convulsive attacks, local and general. The development of the abnormal mental state, however, appeared to be the determining factor in seeking a consultation. Dr. Hannah had been in charge of the case a short time only, and at once recognized the probability of physical disease as a foundation for the nervous and mental manifestations.

The patient was a farmer's daughter, aged 39, single, intelligent and capable up to two years previous to my visit. She had for some years performed important clerical duties as a railway agent and telephone operator at a local station. The family history and surroundings were excellent and prosperous. There was a history of a blow with a croquet mallet on the left parietal region in childhood. There were no sequelæ of importance following this injury; the patient was not unconscious and not confined to the house on account of it. There was no scar at the alleged site of the blow. Two years previous to this examination there had been a "jerking" of the right hand and arm, followed in a few moments by "unconsciousness." These attacks had been repeated about twenty times in the two years just past. Following them was a progressively increasing weakness of the right hand. Two weeks previous to this examination the patient had visual hallucinations and some delusions that surgical operations had been made on her eyes and right leg.

First Examination.—This was made at the home of the patient Nov. 5, 1909. The patient was in bed. Consciousness was somewhat clouded, but the patient carried on ordinary conversation fairly well. She appeared mildly elated, or perhaps a state of euphoria would better describe the emotional state. Asked if she sees anything unusual, she answered "Yes; holes in the ceiling and walls; small ones; many of them." There was no defect in ceiling, nor was it papered. There was nothing to be mistaken for holes; in other words, this was a true hallucination, not an illusion. While the pupillary reactions were being looked for, she volunteered the information that her "eyes had been operated on recently" (probably the opthalmoscopic examination made a few days previously). Asked if anything else had been done, she replied: "Yes, *my right leg was cut off recently.*" This was stated in quite a matter-of-fact manner, without any evidence of regret or emotion. The patient conversed rationally on many ordinary topics, but on being questioned as to any speech defect, she said she "loses a word occasionally." Speech tests showed reception and understanding good for ordinary words. Test-words and sentences were repeated correctly and without defect of articulation. Internal speech appeared good; she could describe objects, letters, words, etc., and tell their meanings. With the practically powerless right hand she could tell the shape of objects, but could not name them (astereognosis). Owing to weakness in this hand, she could not grasp a pencil.

Cranial Nerves: I, not tested; II, ordinary vision, good; no fundus changes reported by Dr. H. P. Shelton, who kindly examined the eyes a few days before my visit; III, IV, VI, no ocular palsies; pupils reacted well to light and accommodation; V, no defects noted; VII, slight weakness in lower right face group; VIII, hearing good to ordinary tests (voice and watch); IX, X, XI, no defects noted; XII, tongue movements good; no trophic changes.

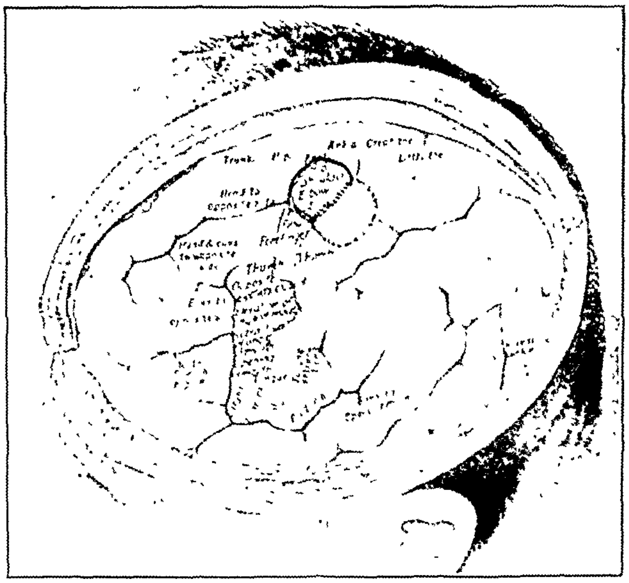

Fig. 1.—Location of brain tumor.

Trunk and Extremities: Motion: Right hand and entire arm useless, relaxed; could bend elbow and wrist and close fingers, but had no grasp; patient could not hold pencil; right leg also weak; could move joints, but could not walk; power in left arm, hand, leg and foot appeared good.

Sensation: No anesthesia to ordinary touch and pin-prick; no differences noted between the two sides of body and limbs.

Reflexes: Organic—Not defective. Tendinous—Knee-jerks diminished, but distinctly present. No difference in the two sides. No spasticity. Cutaneous—Plantar—no response, or occasionally a flexor response; no difference in the two sides.

Trophic symptoms absent; vasomotor symptoms absent.

Diagnosis.—Irritative lesion of the left psychomotor area, probably tumor; possibly a cyst or abscess.

Removal to hospital for further observation and probable operation was advised and the patient was taken to Cincinnati on Nov. 9, 1910.

Second Examination.—Nov. 10, 1910, Ophthalmoscopic examination by Drs. Robert Sattler and Victor Ray revealed no changes in the fundus. Blood examination by Dr. W. E. Schenck, on the same day, showed reds, 4,460,000; whites, 3,600; hemoglobin, 65 per cent.; color index, 0.74.

Differential count: Polymorphonuclear, 81; mononuclear (small) 10, large 5; eosinophils, 4; total, 100.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-First Annual Session, held at St. Louis, June, 1910.

[1] Acknowledgments are due and hereby tendered to Dr. Hannah for kindly contributing his personal notes and observations of the patient.

Diagnosis.—Secondary anemia.

Uranalysis (by Dr. H. L. Woodward): Color, amber; reaction, acid. Albumin, trace (probably due to fecal contamination; disappeared later).

OPERATION REPORT BY DR. KRAMER

First Operation.—Nov. 13, 1909, under ether anesthesia, an opening was made in the skull over the upper half of the left Rolandic area, two inches in diameter. There was no bulging of the dura and no pulsation visible. In the center of the operative field the dura was flattened and darker in appearance. Palpation revealed the presence of a circumscribed mass, harder in consistence than the surrounding cortex. The patient was not very strong before the operation and, as a result of the cranial resection there developed considerable shock. For this reason, the scalp was sutured and the removal of the tumor was delayed for a second operation, after the method of Sir Victor Horsley. After an interval of ten days the patient improved markedly in strength and on Nov. 23, 1909, the second operation was done.

Second Operation.—On opening the dura, we found a tumor imbedded in the brain, adherent to the pia mater, involving principally the precentral convolution and the Rolandic fissure (Fig. 1).

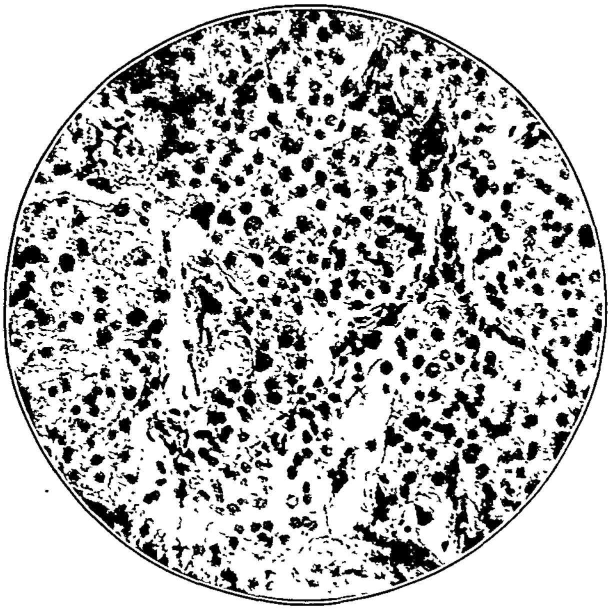

Fig. 2.—Photomicrograph of section of tumor (endothelioma).

The tumor was easily lifted from its bed in the brain, after severing a few slight adhesions to the pia mater. Hemorrhage was insignificant and there was but little shock. At the time of the second operation the brain pulsated very plainly as the result of the previous decompression. The tumor occupied the middle third of the left precentral convolution, growing downward and diagonally backward across the Rolandic fissure and displacing, but not invading, the postcentral convolution. The long axis of the tumor (55 mm.) ran across the Rolandic fissure, downward and backward.

Examination of Tumor.—The tumor was encapsulated, firm and resistant on palpation, presenting numerous small protrusions and cysts on its buried surface. It was not adherent to the dura mater. The tumor weighed 26 gm. and on section proved to be an endothelioma springing from the pia mater (Fig. 2).

The recovery from the surgical procedure was uneventful and the patient returned to her home eight days after the second operation.

Postoperative Notes (L).—Patient put to bed in good condition, conscious; improvement was steady. The hallucinations and delusions had disappeared on the second day. There was no "jerking" in the face, arm or leg. On the eighth day patient could move the paralyzed (right) leg, but could not stand alone. She could move the fingers of right hand, but had no use of it for any purpose. She was removed to her home (forty miles) on a traction car at this time. After arrival home she sat up daily in her chair. Dec. 20, 1909, twenty-seven days after final operation, she took a few steps, with assistance. Jan. 1, 1910, she walked alone across the room.

April 7, 1910, 4½ months after operation, she traveled forty miles on a traction car and called at my office for reexamination, when the following notes were made:

Height, 5 feet 1½ inches; weight, 96 pounds; no mental defect; no speech defect.

Motion: No "Jacksonian attacks," convulsions or unconscious attacks since the operation. Walks well; no defect of gait or station.

Power: Can close right hand, but cannot "register" on dynamometer (standard). Grasp in left hand registers 20 K. Moves right upper extremity freely at all joints, but has little use of hand; cannot oppose the thumb and fingers or make a "fist."

Some "silver-fork aspect" of right hand and wrist. The right shoulder droops slightly. The left sternomastoid muscle is weak, but competent in turning head.

Sensation: Good for tact, pain, heat and cold, everywhere in both hands and arms. Astereognosis *complete* of right hand, front and back, extending half way up forearm. Patient cannot recognize any difference between a pocket knife, finger, coin or wisp of cotton with hand. Half way up forearm on flexor surface she recognizes a silver half dollar as "hard and flat." Some sensory defect in sole of right foot, where cotton and a finger touch feel "the same," but recognizes a touch with a "stick" (toothpick). "Tickle sense" good in both feet.

Reflexes: Organic—No impairment. Tendinous—Knee-jerks slightly plus and equal. Ankle-clonus absent on both sides. Cutaneous—Plantar reflexes, flexor; the right less marked than the left. Oppenheim reflex absent.

Patient goes about the house and grounds daily and attends to personal needs so far as the defective right hand permits. She feels that she is gaining steadily and is cheerful and hopeful generally.

THREE CASES OF TUMOR IN THE CEREBELLO-PONTILE ANGLE *

JULIUS GRINKER, M.D.
Professor of Nervous and Mental Diseases, Chicago Postgraduate
Medical School; Assistant Professor in Clinical Neurology,
Northwestern University Medical School; Consulting
Neurologist to the Cook County Hospital, Chicago; Consulting Neurologist to the Cook
County Institutions at Dunning, Ill.
CHICAGO

Since the subject of tumor of the brain has ceased to have a mere academic interest, and has become the coveted point of attack of every progressive surgeon, reports of well-observed cases have become regular topics for discussion in neurologic and surgical gatherings. From the point of view of successful removal, next to neoplasms situated in the Rolandic area, tumors growing in the angle between cerebellum and pons offer the greatest possibilities for success, and this for two reasons: First, thanks to the labors of modern physiologists and clinicians, the localization of tumors in this region has become comparatively easy; second, the surgical technic has reached a high degree of perfection.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

When, therefore, a diagnosis can be made early and a skilled surgeon is at hand, a perfect result should be obtained in those cases in which the tumor is at all removable. Nevertheless there will always remain a large number in which removal is impossible, either because the tumor is too large, or because it belongs to the infiltrating variety.

Being of the opinion that our failures are sometimes more interesting than our successes, and also that statistics which exclude unsuccessful cases are fallacious, I am reporting three cases of tumor in the cerebello-pontile angle in which the diagnosis was correct, but which were nevertheless failures, if by success we mean with Charles K. Mills not only exact localization, but also the successful removal of a tumor, and at least partial success as regards removal of the disease.

As the entire subject of cerebellar and cerebello-pontile angle tumors has been ably reviewed by Mills, Frazier, Weisenburg and Frenkel,[1] also by Harvey Cushing,[2] and quite recently by Risien Russell,[3] I refer the reader to these authors for a complete account of the varied symptomatology of these neoplasms.

The interest in my report being centered in the cases themselves, I shall follow each case with some general remarks.

CASE 1.—*Patient.*—A. B., aged 24, single, clerk, with negative family and personal history, was first seen by me Dec. 28, 1905. His brother, a physician who accompanied him, stated that, though physically always in good health, the patient has been considered nervous since childhood. At an early age he had suffered from night terrors and even at the time of examination he regularly appeared dazed and confused on awaking in the morning. He was a moderate drinker and smoker and had never acquired syphilis.

Present Illness.—In August, 1905, the patient felt a weakness in the left leg and somewhat later in the left arm, the face was not involved. In the following September he began to suffer from occasional headaches of moderate severity, which were always diurnal, aggravated by physical exercise and localized in the frontal region and the nape of the neck. At about the same time transient attacks of dizziness appeared whenever he rose suddenly from the recumbent posture. Soon thereafter vision began to fail, the eyes were blurred and attacks of blindness occurred, which on passing off, left black spots in his visual fields. Accompanying the disturbances of sight were attacks of dizziness, but never nausea or vomiting. Of irritative motor phenomena the patient described peculiar jerkings and twitchings of the chest muscles, especially marked during excitement. During the month preceding this examination he had been almost constantly tired, the slightest exertion brought on extreme fatigue and sleep was not refreshing, vision had been failing rapidly and the gait showed some staggering to the left. While these symptoms were developing two ophthalmologists were consulted. Each discovered a papilledema and suggested neurologic treatment. The next physician in attendance pronounced the case a functional neurosis. The brother, not satisfied with the diagnosis, brought the patient to my office Dec. 28, 1905, about a month after the previous consultations.

Examination.—This revealed a well nourished young man of average weight and height, whose viscera were normal, pulse regular and 72 beats per minute. Paralysis of any kind was not apparent. Though the left half of the face seemed somewhat relaxed while at rest, yet when the patient was speaking and performing the usual motor tests nothing abnormal could be detected. The left hand grasp was somewhat weaker than the right and the left leg showed a slight degree of weakness when made to move against resistance. The gait was somewhat uncertain and slightly ataxic, with a tendency to reel more often to the left than to the right.

Cranial Nerves.—The olfactory nerves were not involved. The optic nerves showed choked disk and beginning atrophy, in consequence of which vision was markedly reduced. The pupils responded somewhat sluggishly both to light and in accommodation. Nystagmoid jerking appeared when the eyes were directed in extreme lateral positions. The third, fourth and sixth nerves were not involved. When first examined patient made no complaint of paresthesia in the region of the left trigeminus nor was anything found objectively. Two months later, however, corneal areflexia was distinct and analgesia pronounced in the same region. With the exception of a slight degree of relaxation the left seventh nerve appeared normal. A systematic examination disclosed the existence of nerve deafness unknown to the patient and limited to the left side. The cranial nerves from the ninth to the twelfth, inclusive, were not in the least affected.

Reflexes.—All the superficial reflexes were present and of about normal intensity. The deep reflexes in upper and lower extremities were markedly exaggerated, more so on the left side; ankle clonus, Babinski, Oppenheim, or Gordon signs were not obtainable.

Coordination.—Slight static and dynamic ataxia was present in the lower extremities. When each leg was tested separately the greater degree of incoordination was found in the left. The finger to nose test showed marked tremor in the left hand—more of an ataxic than an intention tremor. Cerebellar asynergy in trunk and lower extremities was absent, likewise Babinski's adiadokokinesia sign.

Diagnosis and Treatment.—My diagnosis was tumor in the left cerebello-pontile angle. Immediate operation was recommended with the expectation of saving what was left of patient's vision. The brother having charge of the case successively engaged three surgeons, who performed a number of operations within a period of about two months. The first surgeon trephined over the left cerebellum, but, on discovering the presence of pulsation and no tumor, he replaced the bone and closed the wound. One week later the same surgeon attempted a ventricular tapping but found no fluid. About two weeks later another surgeon was consulted, who also trephined over the left cerebellum. After an unsuccessful search in the region of the left angle he concluded the operation by decompressing the right subtemporal area. Meanwhile the patient had become completely blind. This circumstance caused me to discourage further operative undertakings. Nevertheless, a third surgeon was found who reluctantly yielded to the brother's request to make a new hunt for the elusive tumor. Again the left cerebellum was uncovered and the left cerebello-pontile angle explored. The operation was a bloody one and lasted several hours. In spite of a profuse hemorrhage, which dictated a discontinuance of the operation the surgeon was urged on to continue at any cost. At last his persistence was rewarded by finding a neurofibroma, which he thought probably originated in the sheath of the left acoustic nerve. Because of the patient's precarious condition it was possible only to remove a part of the tumor, namely, a piece the size of a cherry. The surgeon concluded the operation by making subtentorial decompression over the left cerebellum.

Subsequent History.—Recovery from the operation was uneventful and the patient became free from headache and dizziness, but the tumor symptoms were even more numerous and more pronounced. To mention them only, there were adiadokokinesia, reeling gait, left sided motor weakness, optic atrophy, left corneal areflexia, complete paralysis of the sensory trigeminus and left sided deafness. The patient's condition remained practically the same until the middle of September, 1909, when severe headaches made their appearance. These resisted all forms of medication, and surgical treatment was again considered. Dr. Allen B. Kanavel with whom consultation was had, favored a cautiously performed lumbar puncture rather than a ventricular tapping, being fully aware that such procedure has been condemned in tumors of the posterior fossa. A small quantity of spinal fluid was removed, but this sufficed to give immediate relief from headache, the patient was again able to be about as before. Unfortunately this remission was of but short duration for the end came unexpectedly on Dec. 2, 1909. While the patient was conversing over the telephone he had a peculiar seizure, in which he fell backward, striking the ground with his head and becoming unconscious. Coma supervened and he died within two hours after the fall.

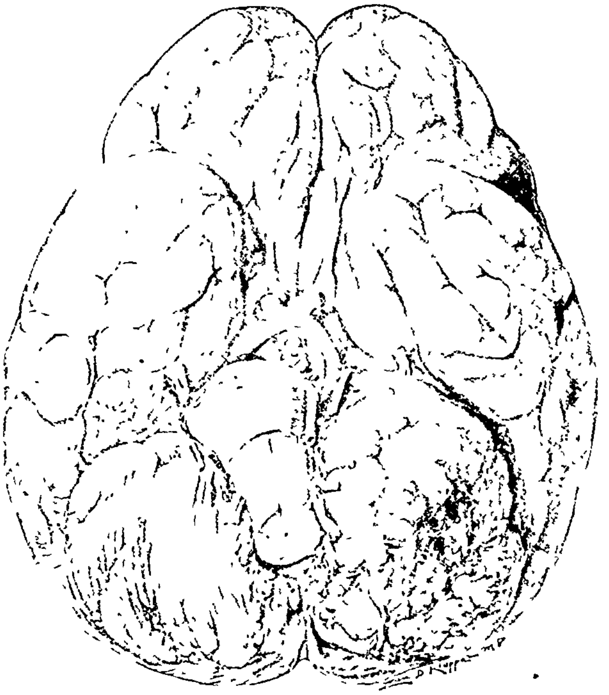
Post-mortem Examination.—Owing to delay in obtaining permission, the brain could not be examined until eighteen hours after death, which, of course, was fatal to the application of the finer neuroglia stains. Macroscopically the brain presented two hernial protrusions: one situated over the right subtemporal region, probably the result of a decompression operation; the other hernia was seen over the left cerebellum, the site of several operations. In my attempt to remove the brain from the cranial cavity I ruptured a cyst containing about six ounces of fluid blood, evidently a recent hemorrhage. The cyst-wall was adherent to the petrous portion of the left temporal bone and constituted a part of the hernial protrusion over the left cerebellum. After hardening the brain in formaldehyd solution neurologic frontal sections were made. With the exception of bilateral internal hydrocephalus, more marked on the right side, nothing pathologic was discovered in the cerebrum. The hydrocephalus was probably the result of obliteration of the foramen of Magendie and of the foramina of Luschka. The conspicuous pathologic condition was in the cerebellum. The entire left hemisphere was occupied by one large mass of denser consistency, but not of different configuration from the normal cerebellum, encroaching somewhat on the structures of the right half (see illustration). A horizontal section through the entire left half of the cerebellum revealed a surface of mottled appearance, strongly suggestive of old and new hemorrhages. Microscopically the sections showed parts in which dense networks of fibrillar ground substance were in close relation with numerous polymorphous cellular elements, varying in size from the small round cell to the long spindle-shaped cell, each containing a granular nucleus. In other parts of the sections could be seen islets of round cells of varying size with scarcely any intervening intercellular substance. In addition there were noticeable throughout the tumor mass numerous vessels of varying caliber. The mottled appearance, previously observed with the naked eye, under the microscope proved to be irregularly scattered hemorrhages of various sizes and ages. For the microscopic sections I am greatly indebted to Dr. C. D. Hauch, and also Prof. F. R. Zeit, in whose laboratory they were prepared.



Enormously enlarged left half of cerebellum, pushing pons-medulla over to the right and containing large glioma.

Pathologic Diagnosis.—Because of the presence of areas resembling sarcoma, and of others corresponding to the appearances of glioma, the diagnosis presented difficulties. There are those who call such tumors gliosarcomata, while others think that this term is merely a cloak for our ignorance. It cannot be denied that rarely both epiblastic and mesoblastic formations may occur in the same tumor, but I incline to the view that most of those reported as gliosarcomata have been either gliomata or sarcomata. It is generally believed that glioma in its varied metamorphosis is capable of producing pictures like sarcoma. The preponderating appearance of my specimen was like that found in glioma; besides, the growth did not overstep physiologic and anatomical boundaries. My diagnosis was glioma cerebelli. In the discussion which ensued on my presentation of the brain with microscopic sections in the joint meeting of the Chicago Pathological and the Chicago Neurological Society, this diagnosis received substantial support.

COMMENT

It is interesting to note that in this, as in many another neurologic case, the ophthalmologists were the first to call attention to the brain as the probable seat of the lesion in a supposed affection of the eye; further, that neurasthenic symptoms had at one period so overtopped the underlying basic trouble that an experienced physician had made the diagnosis of neurasthenia four weeks prior to my seeing the patient, at a time when tumor symptoms must have been present. Another point worth noting is the unusual beginning of the trouble with weakness in the left leg and arm, a weakness which corresponded to the asthenia of Luciani, and was not the result of a motor paralysis, there having been neither disability nor spasticity and pathologic reflexes. The case began, then, with asthenia confined to the left side, without any known cranial nerve disturbances—unless nerve-deafness had existed for some time, of which the patient had no knowledge. Then followed headache, dizziness, and visual disturbances, all general symptoms of brain tumor. Later still came cerebellar incoordination and only after several operations had been performed was trigeminus anesthesia noted.

A retrospect of the surgery in this case brings out the following important points:

1. The presence of pulsation does not necessarily mean an absence of tumor underneath.
2. Once a tumor patient has become blind and his other symptoms, such as severe headache, vomiting and vertigo, are not troublesome, a radical operation may possibly verify a doubtful diagnosis, but is of no service to the patient.
3. A knowledge of the previous point should lead to the performance of "decompression" before blindness has occurred.
4. The much-dreaded lumbar puncture in tumors of the posterior fossæ may occasionally prove beneficial in the hands of those who exercise due care in preventing a sudden escape of the spinal fluid. In this case the removal of only about an ounce of cerebrospinal fluid was sufficient to relieve a headache which resisted all other treatment.

In respect to the discrepancies existing between the ante-mortem pathology, which showed a neurofibroma, and the post-mortem findings, which revealed a glioma, two possibilities must be considered. Either the glioma, which, it will be recalled, contained areas resembling sarcoma, developed since the operation and grew into a previously existing sarcoma—the latter a malignant transformation of remaining fibroma tissue—or else the portion of tumor removed at operation was not a fibroma. Not having seen the first specimen, but having carefully examined the post-mortem sections, I incline to the view that the tumor was a glioma from the beginning.

Equally uncertain is the exact origin of the hemorrhagic cyst. It is quite possible that the fall which occurred when the patient was standing at the telephone was entirely accidental and the cause of the large hemorrhage which produced death by suddenly compressing the medulla. It is more probable, however, that the large hemorrhage was spontaneous and orginated in the same way as did the other numerous large and small hemorrhages, which were not sufficiently extensive to press on the pons-medulla and thereby to cause death. Neither the macroscopic nor the microscopic examination, however, threw any light on this question.

As for the internal hydrocephalus, its occurrence has been frequently noted in tumors of the cerebellum and the cerebello-pontile angle, and has been attributed either to agglutination of the foramina connecting the fourth ventricle with the subarachnoid lymph-spaces, or else to the compression by the tumor of the veins of Galen, preventing drainage of the interior.

Case 2.—*Patient.*—Miss A. C., aged 26, bookkeeper, consulted Dr. R. C. Pattillo in the spring of 1905 for an affection of the eyes. He discovered a refractive error requiring correction with lenses. These having been prescribed, the patient was placed in the care of Dr. Frederick Menge for the treatment of peculiar sensory troubles in the face, presumably caused by antrum disease. Repeated examinations by Dr. Menge failed to disclose the existence of either antrum or sinus disease. The patient was returned to Dr. Pattillo, who made several ophthalmoscopic examinations, and, finding the optic disks normal and no other ophthalmic lesion, concluded that the case required neurologic treatment. Through his courtesy I saw the patient for the first time in July, 1905, and obtained the following history:

History.—The family record, though not of the best, was free from nervous and mental disease, nor could I discover a history of tuberculosis or neoplasm. The patient, never very robust, had always been well until added responsibilities had of late caused a "nervous breakdown." She stated that within the past three months she had developed attacks of sudden blindness, which were momentary in duration and most often occurred when she was recumbent. Though these symptoms at first alarmed her, she continued at work until more troublesome visual disturbances appeared in the form of mists or clouds rising before her eyes, which temporarily obscured her vision while at her books. After a series of these attacks she was obliged to take a few days' rest, but she regularly returned to her work thereafter. A complaint to which she paid little heed, but which had persisted several months before the eye symptoms became prominent, was a peculiar heaviness and pressure feeling, with an occasional sharp pain in the left cheek, often radiating into the left eye. Not infrequently she experienced sensations of "grittiness" in both eyes, followed as a rule by an irresistible desire to sleep. While eliciting this history I discovered marked deafness in the patient's left ear, which, she explained, had come on gradually after more or less constant ringing had persisted in that ear for several months. And finally she laid particular stress on the existence of a feeling of fatigue, especially on rising in the morning, complained of general nervousness and dull headaches, and also of occasional numbness in the finger tips.

Examination.—The patient, an intelligent young woman, of about 26, appearing rather nervous and somewhat depressed, recited her story in great detail and gave it the coloring of the hysterical. A physical examination disclosed normal viscera. Motor paralysis was nowhere discernible, nor could twitching of muscles be seen anywhere. Gait and station were normal. The sensory examination revealed slight hypesthesia over the entire left half of body, including the face. Superficial and deep reflexes were all normal, with the sole exception of some reduction of the conjunctival and corneal reflexes on the left side. The pupils responded well to light and in accommodation. The optic disks were neither congested nor pale; in fact, they appeared typically normal. Hearing was completely abolished in the left and normal in the right ear. Additional findings were: A point of tenderness over the vertex, several such points over the spine and a hypersensitive spot in the left ovarian region. As the symptoms, both positive and negative, were those frequently encountered in functional nervous disease, and as none of the objective signs appeared to me definitely characteristic of organic disease, I diagnosed hysteria and treated the patient accordingly. She visited me several times, seemingly improved at first, but not so during the last two or three visits.

Subsequent History.—In the middle of September, 1905—six weeks after my first examination—the patient entered my office staggering and in a state of alarm. With great consternation she related to me that, as she was crossing the street, she became dizzy, staggered, and everything appeared black to her. It was marvellous, she said, that she escaped being killed, having become blind while crossing the busy thoroughfare. Her sight had gradually returned, but she feared a recurrence of the attack. She also informed me that two days previously she had suffered intense headache, had developed dizziness and had vomited several times. Never before had the last-mentioned symptoms been in evidence. Her gait had become ataxic—a reeling from side to side. The ophthalmoscopic examination revealed to me, for the first time in this case, extreme bilateral choking of the disk.

Diagnosis.—The advent of such symptoms compelled a revision of the diagnosis. Everything suddenly appeared clear to me: The deafness, having come without antecedent local cause and having been preceded for months by tinnitus aurium, could now be readily explained by pressure on the acusticus. And similarly, the paresthetic disorder in the left half of the face, which had given rise to the suspicion of antrum disease, could easily be ascribed to pressure on the trigeminus. The frequent and peculiar visual disturbances, in spite of the presence of normal disks in the early history of the case, could be accounted for by transient attacks of edema. Of course, with the appearance of headache, vomiting and vertigo, added to the cerebellar gait, in a patient who had had acusticus and trigeminus involvement, the diagnosis of tumor in the cerebello-pontile angle on the side of the cranial nerve lesions became almost a certainty.

With this diagnosis and the advice to operate immediately, the patient was returned to her family physician. Two weeks later a two-step operation was performed over the cerebellum, during the progress of which the diagnosis was verified, but the patient died. Consent was not obtained for a post-mortem examination.

COMMENT

In this, as in the preceding case, eye symptoms were among the earliest to attract attention. Paresthesia in the left trigeminus, though antedating the visual disturbances by several months, failed to impress the patient with its seriousness. Likewise, a deafness which was complete—discovered during a routine examination—barely received mention on the part of the patient. To her the visual and neurasthenoid symptoms were of far greater importance, and by manner and statement she succeeded in impressing her physician with a similar belief. This may perhaps explain why manifestations which were unmistakable local signs of tumor in the cerebello-pontile angle, did not receive due consideration until the general symptoms of brain tumor appeared. Further, this case helps to support the following conclusions:

1. Unilateral sensory disturbances, be they ever so slight, should arouse a suspicion of organic disease, because these are not invariably the result of functional neurosis.

2. The focal signs of neoplasm of the brain, and particularly of that growing in the cerebello-pontile recess,

often precede the general symptoms by a considerable period of time.

3. Choked disk may occur late, but rapidly, in tumors of the posterior fossæ.

CASE 3.—*Patient.*—C. T., a woman, aged 55, entered Cook County Hospital on Nov. 26, 1909, in the service of Dr. G. W. Hall, by whose courtesy I am reporting this case. A few days after her admission I made an examination and learned that the patient, whose family and personal history were negative, had been well until about six months previous. At that time she developed dull headaches, which came at irregular intervals, each attack usually lasting several hours. Their localization was principally over the right fronto-parietal region and occasionally over the occiput. Soon after this symptom there appeared more or less constant dizziness, which was always aggravated by the upright posture and by sudden rising from recumbency. Following this, came ataxia of a type which caused the patient, unless supported, to reel and fall mostly to the right, but occasionally to the left and forward. The aforementioned symptoms were rapidly succeeded by attacks of nausea and projectile vomiting having no relation whatever to the ingestion of food. From the beginning of her illness vision had been gradually failing, but she could still read newspapers six weeks before admission; from that time on her sight had deteriorated rapidly, so that at this examination she could only count fingers. An additional complaint was, that six months previously she had developed what was considered a "stroke" on the right side, which left some weakness on the same side.

Examination.—The patient, a well-nourished woman of about 55 years, walked slowly, with short steps, her gait presenting a good example of the intoxicated, but not that of one suffering from past or present motor paralysis. The facial musculature appeared somewhat relaxed on the right side, although on inspection no definite paralysis was detectable. On the application of the usual tests I discovered no noticeable inequality in wrinkling the forehead, but winking was less frequent on the right than on the left side; further, in a voluntary attempt to raise the upper lip, the right half was somewhat retarded, and puckering of the lips as well as whistling seemed impossible. The tongue, when protruded, deviated markedly to the right and the mucous membrane of the right half was thrown into folds, giving the typical appearance of lingual hemiatrophy. With the exception of distinct paralysis of the right external rectus, the ocular muscles showed no anomalies beyond a slight nystagmus, slow in character and most marked when patient looked to the extreme right. The pupils were dilated and responded but faintly to light and accommodation. Vision was reduced to finger-counting. Involvement of the trigeminus was manifest by the presence of hypesthesia and hypalgesia in its entire distribution, including cornea, conjunctiva, nasal and oral mucous membranes. Hearing was entirely abolished in the right and slightly below normal in the left ear. At this point it is well to state that about twelve weeks before entrance an incision in the right external auditory meatus had been made, which resulted in a chronic purulent discharge from that ear. The reason for such treatment was not ascertainable.

Reflexes: The corneal and conjunctival reflexes were absent on the right, present on the left side. Epigastric and abdominal reflexes were not elicitable on either side. Masseter, supinator, biceps, triceps, knee and Achilles tendon reflexes were present bilaterally and were of normal intensity.

Sensation: This was nowhere impaired, except in the right trigeminus distribution.

Coordination: There was undoubted incoordination of both station and locomotion of the variety described as cerebellar: a tendency to fall sidewise when standing or walking, which was not aggravated by closure of the eyes. The cerebellar symptom described by Babinski under the term adiadokokinesia was present and well-marked; the patient was unable alternately to pronate and supinate the right forearm, but could accomplish these movements readily with the left.

The viscera were all normal; likewise the blood and urine, which were frequently examined. A Wassermann test, kindly made for us by Dr. Frederick Harris, proved negative.

Diagnosis.—This was easy in the presence of the many general and local symptoms of brain pressure as found in our case. In addition to the general symptoms of brain tumor, such as headache, nausea and vomiting, bilateral choked disk, there was nystagmus and cerebellar ataxia, which latter symptoms enabled localization in or about the cerebellum. Further, the implication of the trigeminus, sixth, seventh, eighth and of the twelfth nerves on the right side, was sufficient to localize the neoplasm more definitely. When I presented the patient in my Cook County Hospital clinic, I made the diagnosis of rapidly growing tumor in the right cerebellopontile angle, and suggested immediate operation.

Operation.—Dr. Schroeder, of the Cook County Hospital staff, performed the operation on Dec. 17, 1909. A large tumor mass was discovered in the right cerebello-pontile recess, which he considered irremovable. He contented himself with making cerebellar decompression and then closed the wound.

The patient made a good recovery from the operation, but died a few days later—December 27—from the effects of facial erysipelas. Post-mortem examination was refused.

COMMENT

There could have been no difficulties in the diagnosis of a case so rich in classical symptomatology as this one. Only the unusual features therefore will be touched on.

The headache, it will be recalled, was principally in the fronto-parietal region and only occasionally in the occiput, its usual place of election. Had there been no other symptoms, this might have caused confusion in the mind of the examiner and would have created a doubt as to location. It must be recollected, however, that the situation of a headache has but limited localizing value and that in many cases of cerebellar tumor the headache has been entirely frontal.

A symptom which still constitutes a topic of lively debate among neurologists is the muscular weakness occurring in cerebellar and cerebello-pontile angle tumors, some maintaining that it is a real motor paralysis and the result of motor tract involvement, others assigning to it a purely cerebellar cause and explaining it as a sign of cerebellar asthenia. To the latter group of men belongs Luciani, who described three symptoms as characteristic of a cerebellar lesion produced experimentally, namely, atonia, asthenia and abasia. Clinicians have found this triad of symptoms in disease of the cerebellum, and particularly in tumor of that region.

In my last case a diagnosis of cerebral hemiplegia had actually been made because of a rather sudden appearance of right-sided weakness combined with facial involvement. Had the type of facial paresis been investigated, it would have been found to belong to the peripheral-nerve variety, the upper branch being implicated. The absence of pathologic reflexes in the extremities presumably paralyzed, and the uncrossed character of the asthenia—being homolateral with the several cranial-nerve lesions—negatived the diagnosis of hemiplegia and favored that of cerebellar asthenia on the same side as the tumor.

100 State Street.

Multiple Exostoses.—A boy aged 4, when 18 months old, developed symptoms which were attributed to left hip-disease. He was treated with a Thomas' hip-splint for two and a half years. He was then brought to the hospital with a supposed fracture of the forearm. The deformity and limitation of movement at the elbow were found to be due to an exostosis growing from the radius. The patient had numerous exostoses growing from scapula, ribs and ends of long bones.—Harold Burrows, *Proc. Roy. Soc. Med.*, July, 1910.

THE TOPOGRAPHIC DIAGNOSIS OF SUBTENTORIAL BRAIN TUMORS *

HERMAN H. HOPPE, A.M., M.D.
Professor of Neurology, Medical Department University of Cincinnati; Neurologist to Cincinnati Hospital
CINCINNATI

TOPOGRAPHIC DIAGNOSIS

The question as to whether or not we shall operate for tumors in this region, and if we operate, whether the operation shall be radical or palliative, can be decided only by an accurate topographic diagnosis. The subject of differential topographic diagnosis is therefore of prime importance. Surgical intervention is dangerous, or not, in the cerebellar region *in direct ratio to the* amount of exploration, handling and bruising to which the cerebellum is subjected. Moreover, if we know, from the location of the growth, that the chief disturbance produced is by an internal hydrocephalus, as in Case 1, the nature of the surgical interference will be different from that which is indicated if the growth itself, by local pressure, is threatening the life of the patient. More accurate topographic diagnosis will not only enable us to be more precise in advocating or refusing to advise surgical intervention, but it will enable us to say whether the suboccipital or subtemporal region *is to be the seat of the operation*, and, if suboccipital, which side.

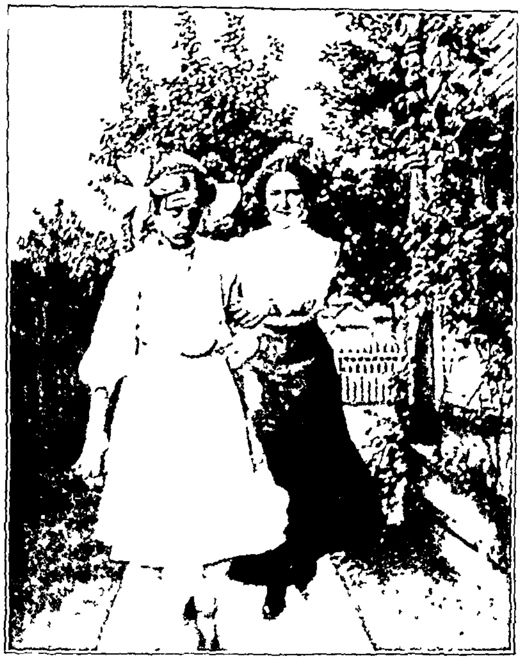


Fig. 1, Case 2—The photograph illustrates paralysis of right external rectus, right facial, and left sided hemiataxia

Have we signs sufficiently positive to enable us to say that a growth is in the brain-stem, in the cerebello-pontine angle or intracerebellar, and if the latter, on which side it is located?

The cerebral surgical triumphs of the last decade have been achieved in relieving cysts and tumors of the cerebellum itself, and those of the cerebello-pontine angle. The diagnosis of the latter growth, as we shall see, is comparatively easy. It is the chief object of this paper to analyze the signs and symptoms which indicate a lesion of the cerebellum itself. I shall assume that such a localization can be arrived at *only by* exclusion, and I shall therefore briefly state the history of cases, in which there were illustrative lesions, which must be excluded in the topographic diagnosis of intracerebellar growths.

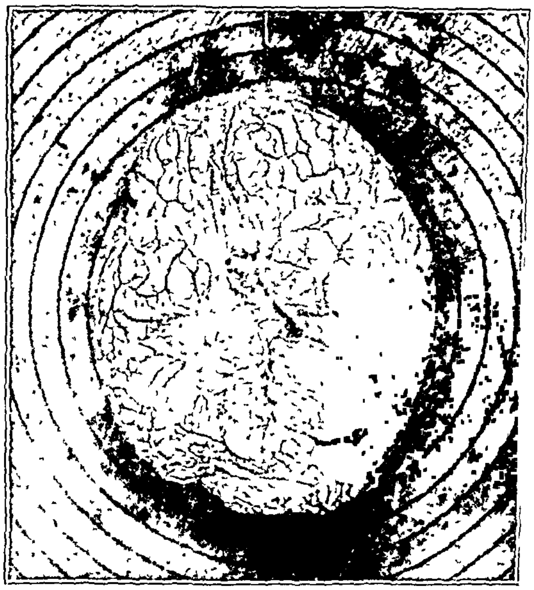

Fig. 2, Case 3—Typical tumor of the left acoustic nerve in the left cerebello-pontine angle.

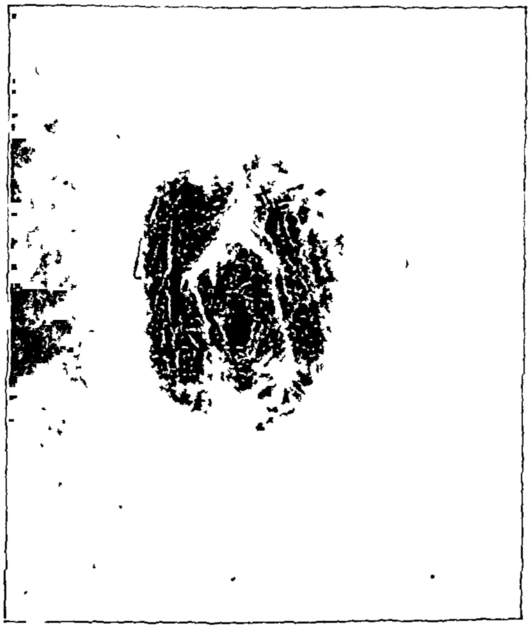

Fig. 3, Case 6—Tumor of the right frontal lobe simulating a cerebellar symptom-complex

TUMORS OF CORPORA QUADRIGEMINA

The first case to which I shall call attention is typical of tumors of the region of the corpora quadrigemina. I shall give but a brief outline of the history, because the case itself will form the basis of a future paper.

We have here a typical case which illustrates the syndrome of tumors of the corpora quadrigemina: Paralysis of the external eye-muscles, involvement of both eyes, inability to turn eyeballs upward, ability to turn them down, pupillary paralysis, ptosis of both lids, blindness, incoordination of gait, some staggering static ataxia; no loss of sensation or of motor power in the extremities. The only discordant note is that deafness is often associated with lesion of the corpora quadrigemina, but in our case hearing remained normal. The other unusual feature is the extreme ataxia which came on toward the end. Patient when in bed used arms and legs freely but was unable to stand at all on account of the ataxia, and showed marked retropulsion on attempting to walk. Intention tremor, athetosis and nystagmus were absent in this case. The autopsy showed that the tumor was practically limited to the corpora-quadrigeminus region.

* For reasons of space, part of this *article is omitted from* THE JOURNAL The complete article appears in the Transactions of the Section and in the author's reprints.

TUMORS OF PONS

Tumors of the pons offer quite a different syndrome from that of the tumors of the region of the corpora quadrigemina as the following case will illustrate:

CASE 2.—*Patient.*—C. W., aged 12, school-girl. Family history was negative. There was no tuberculosis in the immediate family. Patient was well up to four months ago. Onset of trouble was marked by a slight defect in the right eye; patient saw double; at times had some fever; headache occasionally at first; later, more frequent, and just previous to the time she was first seen had attacks of vertigo, and staggered; had vomited every morning. No defect of hearing.

Examination.—At the time of examination the mental condition was normal; pupils equal and responded to light; optic disks normal; there was paralysis of both internal and both external recti muscles; the eyes could be moved upward and downward; paralysis of the right facial, both upper and lower branches; right eye could not be closed. The tongue deviated to left; arms were normal in all respects; in the right leg the patellar reflex was practically abolished; left patellar reflex exaggerated; left ankle-clonus, bilateral Babinski sign; no weakness in legs; hearing normal; when eyes were closed patient walked with a staggering gait, with a tendency to turn toward the left. There was no static ataxia, no ataxia in recumbent position.

Course of Disease.—Two weeks later the condition remained the same, but a horizontal nystagmus had been developed, on looking to right. After four weeks there developed an ataxia of both arms, without any loss of muscular power; with blindfolded eyes patient could not walk forward at all, but invariably was forced toward the left. She staggered to left when walking, and fell to left in Romberg test. Hearing had become defective in the right ear, both to bone and air conduction. Papillæ remained normal; left eye movement upward somewhat diminished; left patellar reflex had returned and both were now exaggerated.

May 24, 1910, mental condition was good; optic discs normal; eye muscles as before; paresis of soft palate; patient choked on swallowing. Right side of face remained unchanged; no loss of sensation anywhere; no areflexia cornea. Speech was difficult; dysarthria was present; patient developed some weakness, but a very acute ataxia of the left side, both arm and leg; adiadokokinesia of the left arm was marked; patient was unable to walk without assistance on account of the left-sided ataxia. Ankle-clonus was present on the left side; exaggerated patellar reflexes.

This case presented the typical history of an infiltrating tumor of the pons. The damage wrought is caused by a gradual destruction of the various nuclei and structures of the pons, partly by invasion, partly by compression.

The symptoms are chiefly bilateral; viz., bilateral involvement of the eyes, bilateral ataxia of the arms, bilateral increase of the patellar reflexes, but the involvement of the seventh and eighth on the right side, paresis of the left leg with ankle-clonus on the left side and ataxia of left arm and leg later on, shows the typical condition of pontine and medullary growths, viz., paralysis alternans.

TUMORS OF CEREBELLO-PONTINE ANGLE

And now let me call attention to tumors of the cerebello-pontine angle. The typical tumor here is of very slow growth, usually a fibroma or endothelioma, growing from the trunk of the auditory nerve; but the seventh and fifth may also be the seat of origin. The typical early syndrome is that of defective hearing on one side, gradually increasing, with occasional attacks of vertigo, with loud noises and ringing in the ear; then the general symptoms of headache, vomiting, vertigo, unsteady gait, plus more or less pronounced involvement of the fifth, sixth, seventh and eighth cranial nerves, on one side, with perhaps an indication of ataxia of arm or leg on the same side, and finally, signs and symptoms which point to a compression of the medulla and pons. This syndrome is so typical that in the majority of cases the localizing diagnosis is easy. Let me here introduce a typical case:

CASE 3.—*Patient.*—R. M. R., aged 49, examined July 9, 1908. Father of four children; superintendent of Normal school, state of Kentucky; patient of O. L. Smith, Lexington, Ky. He had had meningitis (?) when 9 years old; no venereal diseases; influenza yearly for five or six years; had been partially deaf in the left ear for the previous six years. Dr. Smith wrote that in March, 1907, patient had "some contraction of the field of vision, occasional sinistral hemianopia, dextral arm and leg numbness, and inability to nominate with his usual facility." Patient stated that for the previous year he had had occasional attacks of vertigo and could not see out of the temporal half of the left eye; that he could not hear well with his left ear. He staggered at times, but to no special side; lost confidence when he attempted walking in the dark.

Examination.—Mental condition, memory and speech normal; left pupil somewhat larger than the right; both responded to light and accommodation; no choked disk; some weakness of internal rectus of right eye and external rectus of left; horizontal oscillations of eyeballs when turned to extreme left, but no typical nystagmus. The patient could not hear well in left ear, but bone conduction was normal. Sensation in the facial region was normal; reflexes of cornea normal. No loss of function in regions supplied by the other cranial nerves. Sensation, muscular power and reflexes of the extremities normal; no ataxia in upper or lower extremities.

Diagnosis.—No positive diagnosis could be made; neoplasm suspected.

During his vacation patient noticed that his gait was slightly ataxic. In October and November, 1908, he suddenly fell on two occasions. His legs simply gave way under him; was able to arise unassisted and go on with his work.

Feb. 10, 1909, patient stated that he had some headache and vertigo in the fall of 1908; that he was unsteady on his feet and staggered occasionally as if drunk. Six weeks prior to above date he had a sudden onset of violent headaches and vomiting. This continued since; patient was confined to bed and treated for uremia.

Examination.—Patient had not been able to walk without support, and when put on his feet staggered and fell to the left. He was very weak; pulse 96; vomited constantly, and had violent headaches. Pupils reacted to light. Patient had very marked choked disks, but could see well; stated that vision in left eye became blurred occasionally; weakness of internal rectus of right eye and external rectus of left eye; horizontal wavering of eyeballs when turned to the left. (Nystagmus?). He showed a tendency to lie on left side; gait weak and staggering, and fell to the right; no typical cerebellar gait. Nasolabial fold seemed less marked on right side than on the left. No ataxia of the arm; right arm normal in muscular power; the right leg was perhaps a little weaker than the left; urinalysis negative.

Course of Disease.—For two weeks patient stopped vomiting, then vomited occasionally. Seemed much improved on treatment of iodid of potassium. No new symptoms or signs developed for six weeks.

April 5, 1909: Rapid increase, rather suddenly, of weakness in the legs, when put on feet, fell to the right and dragged the right leg. Reflexes of legs exaggerated, had suddenly developed bilateral ankle clonus and slight patellar clonus, plantar reflex normal on both sides, no disturbance of sensation, no ataxia in the recumbent position, no weakness of arms, other signs and symptoms remained as before, except pulse, which was very weak, 120 per minute.

Diagnosis.—Cerebellar tumor, probably on the left side. Dr. Ransohoff was called in to operate. Dr. Zenner also saw the case.

Operation.—On account of the weakness of the patient, it was decided to do a typical subtemporal decompression on the right side, rather than take the increased risk of perhaps a bilateral suboccipital operation. The bulging of the dura was enormous, dura opened and pulsation in brain reestablished, patient left operating room barely alive, on account of cardiac weakness. Twenty-four hours after operation patient suddenly developed a typical tachycardia, pulse 240 beats per minute at heart, irregular, no radial pulse. This condition yielded to stimulation and subcutaneous infusions of salt solution, pulse returning to 108. The bilateral ankle clonus disappeared, headache and vomiting ceased, and patient became comfortable.

Subsequent Course.—On third day paralysis of the pharynx was noticed and up to his death patient was unable to swallow. On the fifth day patient had a convulsion, suddenly lost consciousness, became rigid all over, head thrown back in opisthotonus, radial pulse lost, tachycardia again persistent, respiration suspended, marked asphyxia. Patient recovered consciousness and seemed fairly well with the exception of the paralysis of the pharynx. In twenty-four hours he had a second attack of convulsions, this was followed by tachycardia and quick, shallow respiration. There was a ptosis of the right eyelid, loss of corneal reflex, corneal ulceration on the left eye, no loss of sensation in the left side of face. There was paralysis of the right arm and right leg, and perhaps of the left leg; death.

Autopsy.—This was made three hours after death. The cerebrum was dry and apparently completely drained of cerebrospinal fluid. There was more fluid below the tentorium cerebelli. On removing the tentorium, a tumor, the size of an English walnut, was found partly attached to the petrous portion of the temporal bone, loosely adherent, but apparently growing from the left acoustic nerve. It seemed so soft as to give the impression of being a cyst. The fifth nerve was stretched over the middle of the tumor, anteriorly. The entire cerebellum and brain stem seemed displaced, more especially the left lobe of the cerebellum which was displaced downward and backward. The lower left half of the pons and adjacent portion of the medulla were markedly compressed (Fig. 2).

The case also illustrates the difficulties in localizing even such a typical tumor as neoplasms of the acoustic nerve in the cerebello-pontine angle. Theoretically, this should be easy, but Bruns, Cushing and others have called attention to the absence of signs, and in this case up to within a few days of the operation there were practically no symptoms and signs which indicated with any degree of certainty that the growth was in the cerebello-pontine angle. I believe in our case the extreme softness, almost fluid consistency of the growth during life (although it became quite solid in formaldehyd solution), accounts for the absence of symptoms of pressure, the nerve trunks, being more firm than the tumor itself, were not compressed. Even the fifth nerve, which was stretched and flattened out over the tumor, showed no signs of loss of function, except twenty-four hours before death.

In this case we have typical history of a gradual diminution of hearing in left ear (side of lesion) beginning six years before the tumor caused general symptoms. Horizontal oscillations (jerking) of the eyeballs when turned toward side of lesion. No areflexia cornea at any period before the operation except a few days before death, although the autopsy showed that the fifth nerve was flattened into a ribbon over the tumor. There was no change in sensation, muscular power and reflexes in either upper or lower extremities. There was no choked disk until two months before the operation. In a word for six years after beginning deafness was noticed, no signs or symptoms of tumor of the cerebello-pontine angle were present. A few months before the operation, however, all general and focal signs rapidly set in. Then we have attacks, not continuous, of staggering gait, two attacks of astasia-abasia, inability to walk on account of static ataxia. Patient falls to the left; has no objective loss of power in arms or legs; perhaps a slight weakness of right leg; no ataxia of either arm, nystagmic jerking; weakness of internal rectus of right eye and external rectus of the left. Gait is not typically cerebellar; later on, weakness of right leg develops; bilateral ankle clonus, no ataxia in either upper or lower extremities when in recumbent position; no disturbance of sensation.

BASILAR MENINGITIS SIMULATING TUMOR

In this connection it is appropriate to note another case* which I believe to be a case of basilar syphilitic meningitis, although there is no autopsy report to confirm the diagnosis. Both Weisenberg and Mills have placed similar cases on record. Oppenheim in a recent case report warns us not to place too much importance on a positive Wassermann reaction or on temporary success of the antisyphilitic treatment, in a similar case.

This case was one of a typical syndrome of tumor of the cerebello-pontine angle: General symptoms of brain tumor plus one-sided involvement of the fifth, sixth, seventh and eighth nerves, with ataxia of one extremity on the same side.

The facts, however, that the patient had had a paraplegia six years before which disappeared completely under potassium iodid, and that she died suddenly with all the signs of an acute bulbar palsy, led me to believe that the case was one of basilar syphilitic meningitis. I did not recommend an operation, but placed her on gray oil injections, too late, however, to accomplish any results. This case only strengthens the rule that a careful history and a consideration of the symptoms in the chronologic order of their occurrence is necessary to make the differential diagnosis.

EARLY DIAGNOSIS

I cannot lay too much stress on the early diagnosis of tumors of the cerebello-pontine angle. They are very amenable to surgical treatment, as the numerous cases on record testify, but when the case has advanced to the point of compression of the pons, as in my case, little is to be hoped for from surgical interference. The aurist should be the first to recognize these cases, because of the early involvement of hearing, and should be on the lookout for the early symptoms, viz., progressive loss of hearing with middle ear normal, vestibular attacks of vertigo, slight weakness of face and areflexia cornea on the same side, with perhaps weakness of external rectus of same eye. No other focal lesion, with the possible exception of basilar syphilis, produces this syndrome.

---

* The details of the history are given in the Transactions and in the author's reprints.

After the consideration of these cases we may say that tumors of the cerebello-pontine angle show a predominance of unilateral focal signs on part of the fifth, sixth, seventh and eighth, whereas tumors of the pons and medulla show bilateral focal signs with a clear indication of hemiplegia alternate. In both, the focal signs may precede the general signs of brain tumor, and frequently do. Pons and medulla tumors, being small, produce less marked general signs of brain tumor, whereas, the angle tumors have later on marked general signs. Choked disk is characterized by its absence in pons tumors, although this is not invariably the rule, whereas, the cerebello-pontine angle tumors manifest general signs. Choked disk is almost invariably present, together with headache, vomiting and vertigo, partly due to an associated internal hydrocephalus.

DIAGNOSIS OF CYSTS AND TUMORS OF CEREBELLUM

And now let us proceed to the consideration of that part of our subject which to my mind has the greatest practical importance, namely, the early diagnosis of cysts and tumors of the cerebellum itself. When these tumors and cysts have grown to such a size as to compress the cranial nerves and the pons itself, the diagnosis is not difficult, but the surgical prognosis is bad; whereas, the outlook is good if an early localizing diagnosis can be made before the tumor has grown beyond the confines of the cerebellum. This early diagnosis is very difficult. Not only is it difficult to say whether the growth is located on one side or the other, in the hemisphere, but it is often difficult to rule out the growths of the frontal lobe or to say with certainty whether the symptom complex is caused by a tumor, by acquired internal hydrocephalus, or whether we are dealing with the so-called pseudo-tumor symptom-complex.

CEREBELLAR CASES

Let me briefly introduce two cases here which will illustrate the difficulty of making an early exact localizing diagnosis in cerebellar cases:

Case 5.—*Patient.*—J. P. C., Nashville, Tenn., a man aged 47, single; occupation, sheet-writer. Parents both dead; cause unknown. The patient had never had syphilis or a chancre; had been a drinking man for past ten years, but had never been sick. Onset of present illness eight months previous to examination. The chief symptom was a constant headache, usually occipital, but at times frontal. These headaches were very severe in character, and the periods of freedom were few and short in duration. Any physical strain, and also coughing, made the headache worse. When the headaches were bad the patient was confined to bed, but when he attempted to walk he staggered and showed a tendency to fall to the right.

Examination.—May 30, 1909. The pupils were equal in size, and responded to light. The eyeballs were prominent; external muscles of eyes normal; papillæ normal; corneal reflexes normal; hearing normal in both ears. Left nasolabial fold not so prominent as the right; no defect of function in regions supplied by any other cranial nerve. Muscular power, sensation and reflexes of both upper and lower extremities were normal. There was some static ataxia; marked ataxic gait; patient staggering toward the right.

In the course of the following six weeks there were no new developments, except that the headache and vomiting became worse, to the extent that they were very severe and almost constant. The gait became so ataxic that patient was not able to walk or stand without support. No choked disk developed.

Diagnosis.—Cerebellar tumor, probably of the right side.

Operation.—A suboccipital decompression on the right side was decided on, and the operation was performed by Dr. Horace Whitacre. No tumor was found. The cerebello-pontine angle was explored. The intracranial pressure was very great. About one-third of the right lobe of the cerebellum was removed.

Result.—The immediate result of the operation was a complete relief from headache and vomiting. There was some ataxia of the right hand after the operation. After two weeks the patient was able to sit up, and gradually began to walk. His gait, however, was decidedly ataxic. During the four weeks at the hospital, following the operation, he suffered but one headache. Five months after the operation his condition is fair, but he does not walk much better and has occasional attacks of headache.

Case 6.—*Patient.*—M. M., a woman aged 36, was referred to me by Dr. F. Forchheimer on June 14, 1909. Patient was ill when an infant, but has since been in good health. Had influenza and whooping-cough four years ago. Had influenza nine weeks ago; since then constant headaches; partly frontal, partly occipital, the pain radiating into the shoulders. Had vomiting spells almost daily since the headache became constant. Had vertigo when the head was moved from side to side, or when asked to walk. Vision gradually failed, until patient was unable to read ordinary print.

Examination.—June 14, 1909. Facial expression one of great suffering; slight drooping of left eyelid; bilateral papilledema discovered by Dr. Walter Forchheimer one week ago; no loss of corneal reflexes; slight static ataxia when standing on right foot. The examination was otherwise negative.

During the next five weeks the condition gradually grew worse. Patient had repeated attacks of cerebellar spasms, during which there would be a momentary loss of consciousness, with general muscular rigidity. She also lost the patellar reflexes in both sides, and occasionally had double vision. There was no loss of muscular power in the legs, but the ataxia became so marked that patient refused to walk, but was able to walk with assistance. The vision rapidly grew worse, and a suboccipital decompression was resolved on, the left side being chosen as the probable seat of the tumor, on account of the drooping of the left eyelid and a tendency to stagger toward the left.

Operation.—The operation was performed by Dr. Horace Whitacre. A cyst, about the size of an English walnut, was found at the seat of the operation. It was subcortical, involving the posterior portion of the cerebellum, and on opening it a pale amber-colored fluid was discharged, followed by a collapse of the lobe of the cerebellum. Recovery from shock and anesthesia was rapid.

Results.—Headache and vomiting ceased for a while, and the vision improved greatly, but the other signs remained unchanged. The choked disk continued, the double vision likewise. The patellar reflexes did not return. A sinus established itself automatically, and cerebrospinal fluid escaped in large quantities. After two weeks the headache and somnolence returned. There was an occasional attack of vomiting. There developed an acute ataxia of the left arm and leg, which rendered the patient unable to walk at all. There was also a marked weakness of the left arm. Incontinence of urine and feces developed, and there was a return of the cerebellar seizures. At this time I went away on my summer vacation and left the case in charge of Drs. Whitacre and Langdon. An attempt was made to relieve the patient by draining the lateral ventricles, but the patient died within twenty-four hours after the operation.

TOPOGRAPHIC DIAGNOSIS OF CEREBELLAR TUMORS

The chief interest in the study of the differential topographic diagnosis of tumors below the tentorium cerebelli is whether we have arrived at that state of diagnostic acumen which will enable us to say with any degree of certainty whether a growth is located in the cerebellum itself, and above all, which lobe of the cerebellum is involved. I believe that we can say with some accuracy whether a growth is in the pons, or the region of the corpora quadrigemina, and I believe that the diagnosis of growths in the cerebro-pontine angle can be made with almost equal facility; but the great stumbling-block is offered by tumors of the cerebellum itself. We have seen what signs and symptoms are peculiar to neoplasms of the pons, of the region of the corpora quadrigemina and of the cerebello-pontine angle.

In arriving at a diagnosis of tumors of the cerebellar hemisphere our first step is one of exclusion; we must exclude tumors in the above locations. Then we must exclude frontal lobe tumors. We cannot here go into the symptomatology of frontal lobe tumors, but suffice it to say that there are well known physiologic facts and clinical and surgical experiences which attest the fact that at times it is practically impossible to say whether the tumor is in the frontal lobe or in the cerebellum.

The physiologic fact to which I refer is that the loss or disturbance of function of one cerebellar hemisphere when removed in animal experiments, especially the ataxia, quickly disappears after the operation, but if the animal is then deprived of the opposite frontal lobe, all the cerebellar symptoms return. In a word, the frontal lobe in a measure takes up, or at least compensates for the loss of the function of the crossed cerebellar hemisphere. This interaction of function takes place through the fronto-bridge-cerebellar tract. It is also a well-known fact, that tumors of the frontal lobe, both by causing ataxia, and by producing distance pressure signs, can cause a symptom-complex, which at times can hardly be distinguished from a cerebellar symptom-complex. Moreover, it is not unusual to have unilateral spasms and even Jacksonian seizures in cerebellar lesions, as the cases of Mills and Weisenberg and Case 4 of this paper show, which complicates the matter still more.

FRONTAL TUMORS

Following is a short history of a case of left frontal tumor:

Case 7.—*Patient.*—G. von L., aged 41, was admitted to Cincinnati Hospital Aug. 5, 1901, in a maniacal state, complaining of pain in the left occipital region. He denied venereal diseases and alcoholism. The patient was unable to give a history of his case. According to the wife's statement, he had failed in business six months previously, much worried. For the past six months she noticed a mental deterioration, he did not seem bright, was forgetful. For previous two months he had complained much of pain in the left occipital region. Six weeks before admission, while beating a carpet, patient suddenly staggered backward, was supported to a chair, stared at his wife, was unable to speak, became blue in the face, but did not lose consciousness. At the same time he had a spasm in the right leg, but none in the right arm. The patient said that he felt as if he were going up to the ceiling. He had about ten such attacks that night, three or four the next day and then they became less frequent and finally stopped. This was followed by formication and numbness of right foot. Later he had an attack of paralysis of the right side, which soon passed away and patient returned to his business. There was no headache or vertigo during this period. At times the patient would stagger and show a tendency to fall to the right side, and could not walk without support for the past few days. After a severe attack of pain in the left occipital region a few days before admission, patient had numbness and weakness of the right leg. He began to vomit and had attacks of vertigo. At night he became delirious and in a few days became maniacal and was brought to the hospital.

Examination.—Mental condition was bad, could be aroused from stupor, but was unable to give an account of himself, did not seem to understand the questions put to him, did not speak voluntarily, when asked a question, repeated it slowly, but gave no answer. Paresis of left facial was present, paresis of left side of tongue doubtful, patient was unable to state whether right hand was weak or not on account of mental condition; right leg was dragged when patient attempted to walk. Patient fell to right side. There was no ankle clonus, no Babinski in right side. On ophthalmoscopic examination double choked disk was observed, with hemorrhagic retinitis, right pupil larger than the left, left pupil did not respond to light, right one responded. Slight ptosis of right eyelid, paresis of external rectus of both eyes.

Operation.—An unsuccessful operation was done over left cerebellar hemisphere. Patient died within thirty-six hours.

Autopsy.—Autopsy revealed a tumor the size of a hen's egg, which grew from the dura on the lower surface of the frontal lobe up into the frontal lobe. It was not infiltrating, and the frontal lobe surrounded the tumor like a shell.

This patient was operated on for a cerebellar growth chiefly owing to the fact that there was a hemiplegia alternans, involvement of the external recti of both sides and history of a staggering gait with tendency to fall to one side.

Only recently an autopsy was made in a similar case in which one feature of the clinical history was that the patient at times had a staggering gait. Dercum recently reported a similar case, in which the operation was made over the cerebellum and the autopsy revealed frontal tumor. We are gradually, however, improving our knowledge of frontal growths, as well as of those of the cerebellum. I believe that we shall make fewer mistakes along these lines if we pay greater attention to the chronologic order of the development of signs and symptoms, and I believe that in frontal growths some change in the mental state will occur, and will often even antedate the general symptoms of brain tumor, whereas, *mental symptoms if they occur at all, occur* late in cerebellar tumors. In at least two cases of frontal tumors in my observation the mental deterioration was manifest, the above history showing that the patient at times even became maniacal, and was brought into the hospital in this condition. In the other case, which I refer to above, aside from a progressive loss of vision and the ataxia there were no mental symptoms, except a remarkable euphoria, a cheerfulness which continued to death, lasting over four years, which is certainly unusual in brain tumor cases of other location.

Only recently Reich has shown that we may even have areflexia cornea, which is looked on as a positive diagnostic sign of tumors of the cerebello-pontine angle, in frontal tumors. This, however, is so rare that it need not complicate the diagnosis.

PSEUDOTUMORS OF THE BRAIN

In making the diagnosis of cerebellar growths, we must also rule out pseudotumors of the brain, a subject which has been placed on record by Nonne, Oppenheim, myself and others. This pseudotumor symptom-complex is more apt to resemble the cerebellar symptom-complex than any other. Its pathology is unknown. The autopsy in one of my cases was entirely negative, so far as the brain was concerned. Here is a summary of the typical syndrome: headache, violent vertigo, vomiting, bilateral choked disk, paresis of the external recti muscles of the eyes, areflexia cornea, especially of the right eye, tinnitus, with diminished hearing on the same side, cerebellar ataxia and deflection of head and even entire body to one side. These signs of pseudotumor are in a manner similar to acquired internal hydrocephalus or serous meningitis. These two conditions must be ruled out, and the only means at our command are the presence of other signs and symptoms, on which I shall presently lay stress, which are present in cerebellar cases, and absent in the above symptom-complexes.

PHYSIOLOGY OF THE CEREBELLUM

A few words on the physiology of the cerebellum will be in place here. The chief function of the cerebellum as ascertained by animal experimentation, is that of automatic coordination. Through the medium of the cerebellar tract, Gowers' tract, the posterior column cerebellar tract, and the vestibular nerve, all of which Bruce holds end in the cortex of the vermiform lobe, the cerebellum obtains knowledge of the state of contraction, and the tone of all muscles of the body and the position of the body. When these tracts are interfered with within the cerebellum we have the chief symptom of cerebellar disease, viz., cerebellar ataxia. Lesions of the cerebellum, however, are not the only factor in the production of cerebellar ataxia. We know that tracts lead from the cerebellum to the pons through the corpora quadrigemina and to the opposite cerebral hemisphere, and that the destruction of any one of these tracts will cause cerebellar ataxia. Hence, lesions of the frontal lobe, of the corpora quadrigemina and of the pons may cause cerebellar ataxia. In the lesions of the cerebellum, however, we have ataxia without any associated signs, such as will form part of the syndrome in lesions of the frontal lobe of the corpora quadrigemina and of the pons. In considering cerebellar ataxia and other signs of cerebellar lesions we must not forget, that the loss of function of one cerebellar hemisphere, as Munk and others have shown, may be compensated by the opposite frontal lobe, and that symptoms may disappear; or that disease of one hemisphere may even run a latent course. Babinski lays much stress on a physiologic phenomenon which Munk attributes to the cerebellum, viz., a harmonious interaction between the movements of the extremities and those of the trunk. Babinski calls this function *synergie* and the loss of it *asynergie cerebelleuse.* By this is meant a loss of harmony, which shows itself when walking, for instance, by an attempt to bring the leg forward, while the trunk does not change its position or may even go backward. This symptom was typically illustrated by the tendency to retropulsion on attempting to walk in Case 1, or by the inability in Case 2, of the patient to walk forward when the eyes were closed. *Asynergie cerebelleuse* may be confined to one side—hemiasynergy—as in Case 6; and Babinski says that it points to a lesion of the cerebellar hemisphere on that side or to one of the tracts leading to the hemisphere, or from the hemisphere on that side. Oppenheim seems to agree to this; Spiller dissents. Forced movements are seen in animals, rolling movements, but Munk does not attribute them to lesions of the cerebellum, but to other causes. In the human being we see a tendency to assume certain positions in bed, or to hold the head to one side, the diagnostic value of which we will consider later.

Astasia-abasia, hemiataxic movements, homolateral weakness of muscles, homolateral convulsions, will be considered as localizing signs later on, as will also speech disturbances and nystagmus, all of which have been attributed to loss of function of the cerebellum.

FOCAL SIGNS

What are the focal signs which clinical experience has taught us as pointing to tumors of the cerebellum? The following syndrome calls for analysis:

1. Cerebellar ataxia.
2. Atactic movements, hemiataxia, *asynergic cerebelleuse,* hemiasynergy and tremor.
3. Vertigo.
4. Nystagmic jerking and other eye-muscle signs.
5. Atonic paresis of trunk and extremity muscles on one side.
6. Adiadokokinesia and speech disturbances.
7. Convulsions, unilateral or bilateral.
8. Attitude of the head.

Let us take up the signs and symptoms in the order as they are given:

Cerebellar Ataxia.—The typical, reeling staggering gait is probably seen only in tumors of the vermiform lobe. Perhaps also in quadrigemina tumors (Case 1), but here it will be associated with extensive eye-palsies, which will be absent in the cerebellar lesion.

What is more commonly seen is staggering to one side and a tendency to fall to one side. I believe that when unassociated with pontine signs or symptoms, this may be looked on as fairly characteristic of lesions of the cerebellar hemisphere. It would be of great value, if it could be established as a law, that the patient reels or falls to the side of the lesion. Weisenburg seems to think that this is the case. Two of my patients showed a tendency to fall toward the side of the lesion; one did not. Oppenheim and Siemerling and Spiller hold that we cannot rely on this sign as pointing to the side of the lesion. Siemerling says that cerebellar ataxia may be entirely absent. If the vermis is the seat of the growth, the ataxia may be so great that the patient is unable to stand at all. This is true likewise of growths of the corpora quadrigemina, as Case 1 shows; but in advanced cases, as Nos. 3, 5 and 6 show, may be present in pressure in or on the lateral lobes, or in tumors of the brain stem. But this may be explained by distal or contiguous pressure on the vermiform lobe or cerebellar tracts, in all three of these cases.

Hemiataxia and Hemiasynergy.—These, which Oppenheim thinks may be identical manifestations of cerebellar incoordination, are often present, and may, after further investigation, be found to be of great topographic diagnostic importance as pointing to lesions in the same side of the cerebellum.

Bruns says that hemiataxia is a valuable sign, because it occurs early, and is a sign of an intracerebellar lesion. In the four cases reported by him it occurred in the homolateral arm in each case.

Soques reports hemiasynergy and adiadokokinesia on the same side, homolateral, in a case of tumor of the cerebello-pontine angle.

In Case 3, presumably a pons tumor, very marked hemiataxia, perhaps hemiasynergy, and certainly adiadokokinesia, developed four or five months after the onset of the first symptoms.

The homolateral ataxia which was seen in Case 5 after the operation, is in effect a physiologic observation. No tumor having been found, a large portion of the cerebellar hemisphere was removed, and the homolateral ataxia was noticed after a few days.

In Case 6 there was static ataxia of the right leg (side of cyst), before the operation, loss of patellar reflexes and atony of both legs, but no loss of muscular power. The ataxia became so marked that patient refused to attempt to walk. After the operation the ataxia of the left arm and leg became very acute. In a word, the cyst was found on the left side, and the ataxia was most marked on the left side, the right arm and leg being free. When ataxia is suspected but not present in the ordinary way of standing or walking, Oppenheim recommends that the patient be placed in the ordinary Romberg position, and be asked to bend forward with closed eyes. As a rule, not only will the loss of equilibrium show itself, but also the side toward which the patient sways, will show itself. Some stress has been laid on unilateral tremor of multiple sclerosis, as a sign of cerebellar disease. Collins, Bruns, Siemerling and Oppenheim have called attention to this sign, and when present, it is usually homolateral.

Atonic Paresis.—Atony of the trunk muscles on side of the lesion, homolateral weakness in the atactic limb and loss of patellar reflexes on one side or both, may occur, as seen in Case 6. Bruns says that it occurs only in acute cases after removal of a part of the cerebellum. Siemerling says that it is still a debatable sign. A sudden and acute onset of astasia-abasia, disappearing just as suddenly, was seen in Case 3.

Vertigo.—This, which is invariably present in subtentorial growths, is not of much localizing value. The exact differentiation between vertigo of intra- and extracerebellar origin, as defined by Stewart and Holmes, has not been verified by others and needs further investigation, namely, that in intracerebellar tumors the objects and the apparent movements of their own bodies are from the side of the lesion to the opposite side, and in extracerebellar tumors the apparent movement is toward the side of the lesion. If, however, vertigo is brought about by changing the position of the body or of the head, we may safely say that this occurs when the body or the head is turned away from the side of the lesion.

Nystagmus.—Not the typical nystagmus seen in multiple sclerosis, but a nystagmic jerking, when the eyes are turned to one side or the other, is frequently seen in subtentorial growths. Munk says that strabismus and nystagmus are not seen in animals as a result of the removal of one-half of the cerebellum, but as a result of injuries to the neighboring parts. Siemerling, although admitting it as a sign of intracerebellar lesion, thinks that it is caused by pressure on the pons or corpora quadrigemina. H. Neuman and Collins look on it as a cerebellar sign. Nystagmic jerking is usually seen when the eyes are turned toward the side of the lesion, but this is not the invariable rule. It was present toward the side of lesion in Case 3. It was not present in Case 5 either before or after the operation; nor was it present in Case 6.

Spiller, in a case of cerebellar abscess, says that the nystagmus became more marked when the patient looked toward the seat of the lesion. H. Neuman has conformed this in a later communication.

Siemerling does not feel that the direction of the nystagmus has a positive localizing value, while Oppenheim thinks that nystagmus may be a sign of intracerebellar disease, although it more frequently is the result of distal pressure. I have never seen general ataxia of the eyeballs such as Spiller and Weisenburg describe in a subtentorial tumor, but have seen it in a case of nuclear degeneration of the centers in a case of chronic bulbar palsy.

Attitude.—In this respect, I wish to call attention to the fact that the position of the head and the position of the body have a marked influence on bringing out signs of cerebellar tumors that may be latent. In Case 3 nystagmus occurred only when the eyes were turned toward the seat of the lesion. Oppenheim in a recent article gives his experiences on this subject. He cites two cases of tumor of the cerebellum in which a nystagmus was only slightly indicated when the patients, in a standing position, looked to one side or the other, but which become very marked even when the eyes were at rest, if the patients reclined on one side. In another case in which nystagmus was absent when standing or lying on the back, if the patient lay on his right side and looked toward the left, nystagmus appeared at once, and a paresis of the external rectus became apparent. In another case, nystagmus on looking toward the side of the lesion appeared only after the patient had been turned on a revolving chair, two or three times. In two other cases of subtentorial tumors, areflexia cornea was produced by having the patient lie on the side opposite to the tumor.

Convulsions.—General convulsions or unilateral convulsions, of the cerebellar type, viz., opisthotonos, momentary loss of consciousness with a general clonic spasm of very short duration, are indicative of subtentorial pressure and irritation of the pons, rather than of intracerebellar tumor. They were seen in Case 6 (cyst of hemisphere), as well as in Case 3 (tumor of cerebello-pontine angle). Probably one of the most valuable signs which will indicate the side of the lesion is one to which Babinski has called attention, namely:

Adiadokokinesia.—By this is meant a slowing of movements of an alternating character, and is best illustrated by successive pronation and supination of hand and forearm. In lesions of the cerebellar hemispheres there is a marked diminution in the rapidity with which these movements can be alternated, and occurs always on the homolateral side. Oppenheim and Collins and Siemerling lay much stress on this sign, and especially Siemerling, who says that he always *found it after his attention was called to it.*

Adiadokokinesia, according to Boenhoeffer, who describes speech disturbance in a case of cerebellar tumor, manifests itself as bradyphasia; he says that it is due to an inability of the patient to rearrange his lip and tongue muscles rapidly, which is necessary for fluent speech. Other speech disturbances have been ascribed to cerebellar lesions, as a staccato, jerky mode of talking, which has been attributed to incoordination or ataxia of the muscles of tongue, lip and larynx. Speech becomes slow, repetition of long words causes a chopped-off reproduction, and at times stumbling and stammering. Rapid speech is impossible, but there is no anarthria. The attitude of the head may give us some indication as to the side of the lesion. Baten called attention to the fact that the head is inclined in such a way that the occiput points to the side of the tumor, and the chin is pointed away from that side. Collins, in a case of hemorrhage, describes just the opposite condition. Oppenheim says that there is no rule, but that the patient assumes such a position of the head and body as cause him least inconvenience. Spiller also thinks that there is no rule. In my cases I could not confirm the rule. Sholz has used the Neisser puncture test to determine the side of lesion, and located the tumor in two out of three cases by this means. Oppenheim calls attention to a difference in the percussion note on the two sides, and says that we may find more dulness on the side of the lesion. Bruns calls attention, especially in children, to tenderness on percussion, and the cracked-pot sign, on the side of the lesion.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. HOPPE, LANGDON AND KRAMER, AND GRINKER

Dr. C. H. Hughes, St. Louis: Papers of this character are always exceedingly interesting from the light they give us on the subject of diagnosis. Symptomatically in all we have choked disk *and titubating, unstable gait. No paper has yet* been given presenting a case so markedly unilateral as to give us that characteristic symptom in the gait, of a disposition to describe a semicircle in the walking of the patient.

The subject of brain tumors becomes especially interesting for the purpose of diagnosis, particularly focal diagnosis, as they impinge on the origin or a course of certain cranial nerves. Tumors of the *posterior portion of* the brain and cerebellum often result in loss of vision which is quite characteristic, but the tumor in the white matter of the brain causes choked disk only from the general involvement of the brain, and its congestive condition apparently, so far as my observation has gone.

When as a surgeon, I was called to preside over a hospital for the insane, I used to think that it was the province of a surgeon to operate in every case when opportunity offered, especially for epilepsy and tumors. But I am not so hasty now in operative suggestion. I recall an instance of unilateral involvement *of the cerebellum accompanied by the* characteristic tendency to describe a circle on the opposite side of the lesion in attempting to walk, I was agreeably surprised in that case, after the use of extensive doses of cathartics and sodium bromid, etc., to see that symptom disappear. Notwithstanding, the man died and I made the autopsy which McLean Hamilton reproduced in his classical work on that subject at the time. *We have not all the light that is coming to us yet* on the subject of tumors, but we are getting more light than we had some years ago.

Dr. G. W. Hall, Chicago: In one case that Dr. Grinker reports, the patient, who came on my service at the Cook County Hospital, showed the typical findings of the process in the right cerebello pontile angle, and the question at that time so far as the diagnosis was concerned was whether or not there was an abscess or tumor. As Dr. Grinker brought out in the history of the case, it was at first very puzzling, because the patient had also a discharging ear, but the fact that the ear *had been punctured by a physician, on the outside, at a* more recent date than the onset of the symptoms, easily cleared up the history, sufficiently to guarantee the advisability of an operation.

In connection with that case I might mention also the conditions which Dr. Hoppe brought out as to frontal tumors. No one can make an absolutely accurate diagnosis as to localization of tumors of the brain perhaps outside of the cerebello pontile angle. We have seen instances occur in which diagnosis of cerebellar processes have been made, and the processes were found in the frontal lobe or in the brain proper.

Dr. Hoppe's statement as to the mental symptoms occurring in the frontal tumors rather than in the cerebellar tumors seems to be a point well taken. That was especially dwelt on by Dr. Beevor in one case he had on his service in the hospital at Queen's Square, London, in which he made the probable diagnosis of a frontal tumor rather than a tumor of the cerebellar process because of certain mental symptoms present in that case.

Dr. Charles L. Dana, New York: A few years ago the subject of brain tumors had become interesting, because the success of surgical intervention was so poor, but in the last four years we have been much more successful in localizing *and removing tumors, especially subtentorial tumors.* In historical justice to American neurologists, Dr. Grinker ought to state that the attention to the clinical facts regarding tumors of the cerebello pontile angle, was first brought out by Dr. Hunt and Dr. Franckel about four years ago in a series of papers and reports which they made at that time, it antedated any emphatic recognition of these tumors by any foreign or American neurologist or surgeon that I know of. At that time they reported several cases and three operations, all unsuccessful, but they then drew attention to the fact of the ease with which such tumors can as a rule, be recognized. One point which they made was that in some of these patients there was a neurofibromatosis of the skin, so that in some cases the possibility of a tumor of the cerebello pontile angle was suggested by the fact that a great many little fibromas of the skin had been noticed in the patient.

There is a symptom in cerebellar disease sometimes seen in tumors, hemorrhages and softening and atrophic conditions, that is, a certain *tendency to catatonia.*

The cerebellar seizures that have been referred to vary somewhat in character, but are most frequently, I think, either sudden plunges forward or sudden droppings down by the patient as though he had been struck by lightning, or suddenly fainted, at other times the patients fall down and assume the sprawling attitude and tonic spasms such as are seen in animals *experimentally operated on.* These cerebellar seizures generally come from lesions that begin from an extramedullary source—tumors of the pontile angle or of meningeal origin.

Dr. Theodore Diller, Pittsburg: Those who attended the Section last year at Atlantic City will remember a patient that I showed before the Section at that time, from whom a cerebellar tumor had been removed. This patient suffered from very severe headaches, showed a high grade of optic neuritis, 6 or 7 D., and had a posture of the head to the left, away from the tumor. The tumor was removed from the anterior margin of the cerebellum after about one third of the cerebellar lobe had been removed. I saw this patient about a month ago; he is working on a farm. His gait, which was extremely uncertain, is good. He is entirely free from pain. He says that he sees well, and is comfortable in every way, and the only thing that we can discover wrong with him is a moderate grade of optic atrophy. This case is now of about eighteen months' standing.

I commend very much Dr. Hoppe's method of presenting his case here today by the pictures. It is difficult to transport specimens to a meeting, but stereopticon views like these give as plain a perspective view of the tumor as the actual specimen would.

With regard to this point of the confusion between frontal and cerebellar lesions, let me say that recently I saw a patient whose history was that he had fallen, and that an operation had been done in the frontal region, and a small amount of pus removed a year ago. When I saw this patient he was having a *great deal of pain in the occipital region, he was complaining* of very severe pain confined to the frontal region and his head was extended backward very far. He had no fever; and he had not the slightest pain in the frontal region. We hurried him off to the hospital. An operation was done over the frontal region and an abscess was found immediately below the site of the old wound, and I think fully an ounce of pus came out. The case is very striking. The only thing the man complained of was very severe pain in the occipital region (not localized as to the side—probably bilateral), and this was due to an abscess in the frontal lobe.

Dr. D'Orsay Hecht, Chicago: The interest taken in cerebellar neoplasms and the discussions arising therefrom, have resulted in a gratifying percentage of accurate localizations in operations in this region. This is particularly true of cases with acusticus symptoms. As soon as a suspected tumor presents in a marked degree eighth nerve involvement, the tendency is to designate it as a cerebello pontile angle tumor. I should like to get some expression from the members with *regard to* the propriety of calling tumors, necessarily wide spread in their extent over the cerebellum or in the cerebello pontile space, angle tumors. We are in truth not dealing with an angle, so far as the invasion by tumor of this area is concerned. We are rather dealing with a quadrilateral space, something that has more of the configuration of a rectangle. I feel, therefore, that if we get away from the designation of angles in these cases we may be serving cranial topography with more accuracy, so far as this site of predilection for certain tumors is concerned.

In Dr. Grinker's paper, I think that, aside from the complete report of his cases, chief interest centers in the character of his summary, in which he dwells upon the question of glioma and sarcoma, as well as the expediency of lumbar puncture. I think that we as neurologists are quite agreed that lumbar puncture of itself is a relatively innocuous adjunct to our diagnostic technic, but it may prove a decidedly dangerous measure in the presence of a brain tumor. Perhaps this particular fact is not sufficiently impressed on internists or general practitioners. I have not infrequently heard physicians who busy themselves more or less with the modern routine in neurologic examination, ask whether a lumbar puncture has been made, forgetting, I think, that lumbar puncture may be of real danger to the patient when we are dealing with obvious symptoms of intracranial pressure of tumor origin. I should advise extreme conservatism in doing lumbar puncture in this type of case.

I think, too, that in those cases in which cerebral tumor of solid formation is suspected, we are not infrequently surprised to find a cyst, capable of evacuation, and therefore yielding a better prognosis than was admissible from the premises prior to operation. I recall such an experience five or six months ago, when it was my privilege to see a case of brain tumor at the request of Dr. Alfred Murray. I made a localization of cerebellar tumor and the patient was operated on by Dr. Albert E. Halstead, of Chicago. The acusticus findings were of very material value in referring the tumor to the cerebello-pontile space (or angle, if you wish) and on a very extensive decompression, exposing both sides of the cerebellum very widely and spaciously, it was found that the suspected area was filled with a fairly large cyst, which was properly evacuated, and at a recent date, the patient was doing very well in his own home, and able to be up and about, for a time even following his occupation as a pharmacist.

I agree with Dr. Dana that we should not forsake the old and well-tried clinical criteria in arriving at a localization, but, on the other hand, I feel that we should put due emphasis on some of the newer additions to our technic and credit with importance such a symptom as, for instance, has been advanced by the French school, and called "adiadokokinesia." I have noted it in several instances, and I think, as an evidence of asynergy, it is quite as important as are other symptoms entering into the question of the coordinating function, as it depends upon the cerebellum.

Dr. Julius Grinker, Chicago: I wish to emphasize a point of general practical interest, namely, that hysteria and neurasthenia are diagnosed often in cases requiring more extended investigation. I recall several such cases of my own, in which the symptoms at first pointed to functional disease, but brain symptoms developed later and the diagnosis of organic disease had to be made.

One point which has not received due emphasis in this discussion is that cerebello-pontile angle tumor may begin with hemiplegic symptoms. My third case, which for lack of time could not be reported in full, was diagnosed as hemiplegia at a time when there were hemiplegic manifestations in the form of one-sided asthenia, that is, a unilateral weakness resulting from cerebellar atonia. In these cases there is neither exaggeration of reflexes, nor Babinski sign.

I am very thankful to Dr. Dana for correcting my short reference to the historical development of this subject. It is quite true that Drs. Hunt and Franckel were the first to call attention to tumors in the cerebello-pontile angle; they also furnished splendid contributions to the symptomatology.

In my opinion the new cerebellar sign described by Babinski under the term "adiadokokinesia" is not valueless. When present, *it is a reliable sign. It is more often absent than* present and frequently it only appears after an operation has been performed on the cerebellum, certainly too late to be of value in diagnosis. In one of my cases this symptom was present before any of the others. While, then, this sign may not be of the greatest value, we may nevertheless consider it, if only the observation may serve to determine its proper place in the symptomatology of cerebellar tumor.

Staggering to one side is not a reliable focal sign. In two of my cases the staggering was on the side of the tumor; in the third case the patient staggered to either side.

Concerning speech disturbance, my first case showed an utterance which might be called "jerky" speech, rather than bradyphasia. The so-called "cracked-pot" resonance I have not found in my cases, but I have often observed it in the hydrocephalus of children.

EHRLICH'S BIOCHEMICAL THEORY, ITS CONCEPTION AND APPLICATION *

LOUIS HART MARKS, M.D.
Fellow of the Royal Institute for Experimental Therapeutics
FRANKFORT A. M., GERMANY

It is my privilege in this paper to take up the subject of specific chemical therapeutics, which is equivalent to saying that I am to expound the work that Professor Paul Ehrlich has accomplished in the past seven years, during which time he has done far more than merely lay the *foundation of this new science*. It can be said that this basic idea, which he has followed logically from the very beginning of his experimental work, down through his present world-stirring discovery; namely, that a specific chemical affinity exists between specific living cells and specific chemical substances, is his main, most valuable, broadest and most suggestive contribution to science.

It was this idea that was at the foundation of his famous studies on the morphology of the cellular constitution of the blood. As is known, Ehrlich was the first to describe correctly the leukocytes, and to teach us to differentiate not only different parts of the body of the leukocyte from one another, but also the different kinds of leukocytes one from the other, by showing that these different parts stain differently with the same dyestuffs.

Following up this work in the field of morphology he studied vital staining and demonstrated even more clearly the selective action of many different substances for different tissues of the body. The best-known experiment in this connection is the one performed with methylene blue, whereby he showed that if the substance be injected directly into the circulation, on section of the animal some time later, the tissues of the nervous system will be the only ones colored blue. He found further that those cells of the body which demand the most oxygen would not be colored at all, but would turn blue after an exposure to the air. This led to the publication of a work[1] which stands out as a beacon light in the realm of science, and is surpassed only by his original publication of his fundamental theory concerning the distribution and selective action of chemicals in the human body.

Further following out his idea he happened to feed mice with ricin and abrin, the vegetable poisons contained in the castor oil and jequirity beans, and found that he could immunize them against these poisons. Not only was this the first time that animals were highly immunized to vegetable poisons, but it was also the first time that the degree of immunity was definitely known. He also discovered the coagulative action of ricin on the red blood-corpuscles and found that he could prevent this by adding to a mixture of ricin and red blood-corpuscles a small quantity of the blood-serum of a previously immunized animal.

---

* Delivered by invitation before the Anglo-American Medical Association of Berlin, Sept. 10, 1910.

[1] The Oxygen Requirements of the Organism.

As the opportunity was given to Ehrlich to follow out on a large scale researches that he had long hoped to be enabled to carry on, and to which he was much more forcibly attracted, he left the other fields of research to undertake the study of specific chemical therapeutics.

Ehrlich believed (and this belief found sufficient support in his twenty-five years of experience) that for each specific parasite a specific curative drug must and could be found.

An important question to be solved in starting this work was the selection of a suitable parasite and a suitable animal for experimentation.

Because of the sleeping-sickness epidemic in Africa, and because the trypanosome is easily transferable to mice, Ehrlich began working with trypanosomes. At first he used many dyestuffs, some entirely new, some old. He soon succeeded, in connection with Weinberg, in producing a new dyestuff, trypan-red, which absolutely cured every infected mouse with one injection. This was the first time that a living organism was completely sterilized; that is, that every one of the parasites within the body was completely destroyed by a disinfectant.

The complete sterilization of the animal's body with trypan-red was but the first step forward in this new science. It was found that if a slightly smaller dose was injected than was necessary completely to destroy all the trypanosomes, then these would entirely disappear from the circulation for a period directly proportional to the dose given, but after that period they would again return. If the mouse were again injected with the same dose, the parasites would again disappear only to return after a shorter interval. If the injection was repeated several times, a strain of trypanosomes would be obtained on which trypan-red had not the slightest effect. In other words, the parasites became completely resistant to the largest dose of trypan-red that it was possible to inject into a mouse without causing injury to it, and this resistance was transmitted to the trypanosomes for many generations. It is possible that if a strain of trypanosomes could be brought to the maximum immunity towards a given drug, this characteristic would become constant. For example, we have in our laboratory a strain of trypanosomes which nearly four years ago was made resistant to atoxyl, and is still resistant after three and one-half years passage through normal mice.

And again, I have succeeded after three and one-half years of arduous work in producing a strain of paratyphoid bacilli resistant to arsenious acid. I have grown them on agar containing increasing quantities of the drug. At first a dilution of 1 to 28,000 was sufficient to prevent the growth of the bacilli, but now they grow freely on an agar containing a dilution of 1 to 3,500. The chemical receptors of the bacteria as well as the agglutinative receptors are entirely different from those of the original strain; for instance, the resistant strain is completely resistant to antimony, which the original strain is not. At first when the dilutions were very great it was easy to bring the strain back to normal by passing it several times on ordinary agar. However, we have passed a highly resistant strain on ordinary agar 150 times, without succeeding in bringing it back to normal.

The demonstration that these parasites could so readily become resistant to different chemical substances led to the logical conclusion that in order permanently to cure a parasitic disease it is necessary to destroy in the shortest time every single parasite with one injection of a drug, as it can readily be seen that if complete sterilization is not achieved, and frequently repeated doses are necessary, the substance would soon lose all effect, and the person or animal treated would then be worse off than before the treatment was begun.

This, then, became Ehrlich's aim: to produce a substance which was so specific for given parasites that they would be completely destroyed by one injection.

Just as a general to make sure of victory when trying to capture a fort on a hill attacks it from all sides, so Ehrlich went to work. As the parasites have many receptors specific for different groups of substances, many different substances are tried out; in other words, a combination treatment is aimed at. Therefore Ehrlich has striven in the last few years to produce more than one drug which would act as specific on the same parasite. This combination treatment also has the additional advantage that much smaller and less dangerous doses can be given than would be necessary if the maximum tolerable dose of one drug were used.

As has always been the case in the treatment of diseases, all possible drugs were tried on animals and people infected with trypanosomes. Bruce was the first to find that arsenic was a drug of appreciable value in the treatment of surra (trypanosomiasis of horses). Soon after Ehrlich started his work on trypanosomes, Thomas found that atoxyl, a compound of arsenic and anilin, would cure a large percentage of infected laboratory animals. Then Kopke used atoxyl in the treatment of human sleeping-sickness in Africa. Ehrlich started to work with atoxyl and found that it was an entirely different substance from what Béchamp, its discoverer, had thought it to be: instead of the arsenic being connected directly with the nitrogen of the anilin, and instead of this combination of anilin and arsenic being a very loose one, the arsenic was directly connected with the benzol ring of the anilin and the combination was a stable one and capable of entering into many different kinds of substitution products.

Almost at the beginning of the work it was discovered that although trypan-red possessed the power of destroying all the trypanosomes in the body of a heavily infected mouse, it had no effect whatever when mixed in a test-tube with a blood-suspension containing trypanosomes even in the strongest dilution. It was also found by Mesnil that atoxyl, which caused the trypanosomes to disappear within several hours from the circulation and glands of patients suffering from sleeping-sickness, possessed absolutely no effect on trypanosomes outside of the body in a test-tube. These two phenomena Ehrlich designated as a paradoxical or indirect action.

In order to explain this phenomenon it is necessary to glance over the general theories underlying this science as they have frequently been expounded by Ehrlich. First, what are the drugs that come under consideration at all? and then, how are these drugs effective?

Of these drugs there are three groups:

1. The arsenic group, examples of which are arsenious acid, atoxyl, and later the new atoxyl substitution products, such as acetylatoxyl, arsenophenylglycin and dioxydiamidoarsenobenzol. To this group can also be added the antimony compounds.

2. Certain azo-dyestuffs, such as trypan-red, discovered by Ehrlich and Weinberg, and trypan-blue and trypan-violet, discovered by Mesnil.

3. Certain basic triphenylmethan dyestuffs, such as parafuchsin, methyl-violet and pyronin.

The mode of action of these different drugs varies, according to Ehrlich, as follows:

1. Some substances have *no effect on the parasite* in test-tubes and possess no curative properties; in other words, the trypanosomes possess no receptor which fits into the atom grouping of the substances.

2. The substance has a highly destructive action on the parasites outside the body; but has absolutely no curative effect. This is best illustrated by the experiment of Koch with anthrax bacilli and bichlorid of mercury.

3. The substance has absolutely no effect on the parasites outside the body, but shows a highly or completely curative action when within the body. This is the indirect *action which I have just spoken of, and under this* category can be placed most of those drugs which are of practical interest.

Ehrlich has now brought forth sufficient proofs that this paradoxical or indirect action, which many other dyestuffs and arsenic compounds also possess, is due to one of the following conditions:

The first condition is that the substance, which outside the body has no effect on the parasites, is so changed in the body that it becomes effective. In the case of atoxyl Ehrlich has proved that the effect is due to a reduction of the substance within the body, and that the reduced substance is probably a compound called paramidophenylarsenoxyd. This substance he manufactured in the laboratory by reducing atoxyl, which then destroyed the trypanosomes in a test-tube in the amazing dilution of three or four millions. He theorizes from the results which he has obtained with many hundred arsenic compounds that the trypanosomes have a receptor which will combine only with three-valent arsenic and not with the five-valent arsenic, as it is present in atoxyl.

The second possibility of the indirect action is due to an inhibition of certain functions of the parasite which have to do with its reproduction or the destruction of some of its constituent parts. This is shown by the often repeated experiment in which, when trypanosomes are mixed in test-tubes with weak dilutions of certain basic dyestuffs, the trypanosomes continue to live and move, but if this mixture is injected into a mouse no infection will take place. B. Busk also proved the correctness of this by showing that certain paramecia live for many weeks in a strong solution of trypan-red but fail to multiply as usual.

A clinching discovery was that of Werbitzki, working under Ehrlich, who found that if trypanosomes were treated with certain dyestuffs (pyronin) they would lose very rapidly their blepharoplast, and that this characteristic was inherited by the offspring for many generations.

This brings us to the consideration of the several methods by which specific substances can bring about a lasting cure. Either the drug destroys all the parasites within the body by its direct and specific action, or the curative substance need kill only a certain number of the parasites, when the remaining ones will be destroyed by the rapidly formed antibodies, as has been shown by Wassermann, Schilling and Mesnil.

These are some of the fundamental theories on which a mighty structure has already been erected. Let us turn now to the practical results achieved.

Trypan-red proved a curative agent only for mice. It had no effect when used in the treatment of larger animals infected with trypanosomes. Since then it has been found by Manteuffel and Uhlenhuth to have a distinct curative action on some forms of spirilla. Nuttall has found that trypan-red is a most effective remedy in the treatment of a widely distributed disease of cattle, *known best under the name of Texas fever. It* has been possible to produce a drug known as arsenophenylglycin which absolutely and lastingly cures with one injection of a proper dose all animals suffering from trypanosome-infection. It has been tried on human beings suffering with sleeping-sickness with varying success. In West Africa von Raven has succeeded in curing a number of cases of human sleeping-sickness with a relatively small dose. On the other hand in East Africa, where the epidemic really is at the present moment, the results have not been so promising. It is hard to imagine what a difficult thing it is to obtain *satisfactory results when the field of action is so far* distant; and more important still, when the dose of a new drug that a human being can safely stand is absolutely unknown.

This can be better appreciated when we know, for instance, that the largest single dose of arsenophenylglycin in East Africa has not exceeded 1 gm., whereas lately in the Congo, Broden has given as much as 4 gm. in one injection. Frequently the specific instructions given by Ehrlich are misunderstood or the individual worker tries out his own theories. It has been Ehrlich's wish that the largest possible dose be given in one injection in fresh cases of sleeping-sickness, that have not been previously treated with other arsenic preparations, principally atoxyl. Notwithstanding these specific instructions many cases have been treated in the later stages of the disease in which permanent changes in the nervous system have already taken place or where the eye has already been damaged by a previous atoxyl treatment. Hence the results are variable and it is easy to see why any statement as to the ultimate value of this drug must be of the most conservative nature. Until a large number of fresh cases of sleeping-sickness, in which the trypanosomes have not yet invaded the spinal canal, are treated with the largest possible dose that can be given to a human being without injuring the body, our final conclusions must be withheld. At the present time in Africa two dyestuffs, trypanosan and agridinium, trypanocidal substances of very great value, are being used in combination with the arsenophenylglycin.

After having produced this latter drug and after it had been shown that syphilis could be transferred to rabbits, an animal that is easy to work with in the laboratory, Ehrlich turned his attention to that group of diseases caused by the spirilla: syphilis, relapsing fever and chicken spirillosis. Only a short time elapsed before dioxydiamidoarsenobenzol, better known as "606," was brought forward. Hata soon found that this drug definitely cured chicken spirillosis in a dose fifty-eight times smaller than the *dosis tolerata*, or the largest dose that could be given with safety to any animal. The spirilla of relapsing fever when present in the body of a mouse were also easily killed by one injection of a small dose. One-seventh of the *dosis tolerata* was sufficient to cure a rabbit infected with syphilis. This relatively small dose caused the *Spirochæta pallida* to disappear completely from the lesions within twenty-four hours. After repeatedly securing these results, Ehrlich decided carefully to start some trials with the substance on human beings. First of all, the drug was sent to Professor Alt, who tried it on dogs, and then on two of his assistants, who volunteered, in order to make sure that it would have no evil effects. It was then tried on patients. To Iversen in Russia, Ehrlich entrusted the substance to treat human cases of relapsing fever, which he did with signal success. With one injection of 0.3 gm. Iversen was able to cure completely for the first time relapsing fever in 90 per cent. of his patients. Within a few hours after the injection, the patient usually suffers a chill of greater or less severity, followed by profuse sweating and a rapid decline of the fever to normal, at which point it remains indefinitely. The action of this drug on such an important disease as relapsing fever we must not allow to be overlooked in the fury and clamor concerning its action on syphilis.

Now to that which no doubt interests us mostly: the results of the treatment thus far obtained in cases of syphilis.

In order to be absolutely sure of his ground and to know exactly when, how, and how much of this substance could be given, Ehrlich has given away over 20,000 doses free of cost to more than 500 selected physicians throughout the world. And all he asked of them was to treat certain classes of patients (which, by the way, many of them have not done), under certain rigid restrictions which he laid down, to the effect that all patients must be confined to bed in a hospital for several days after the injection in order to be under careful observation; that only syphilitics who have healthy hearts and kidneys and sound eyes, that is, in whom no degeneration is present, be treated. From these physicians he now has records of about 6,000 cases and at least 2,000 additional patients have been treated, whose records have not yet been sent in.

The great majority of investigators are astounded at the completeness and rapidity of its action. Naturally some bad results have already been reported, but to find the cause of this has been an easy matter. For instance, we heard some time ago, that certain investigators had seen in a remarkably large percentage of cases paralysis of the bladder and rectum. As soon as their technic became known it could easily be seen that the symptoms were those of methyl-alcohol poisoning, this having been used in too large quantities to dissolve the drug, and possibly being impure at that. It is remarkable that in some of these clinics where hundreds of patients have been treated, no evil effects have been found (aside from a few necroses due to a too superficial injection of the drug, usually when given in suspension). It must also be impressed on every one that Ehrlich has never claimed that this drug is harmless. On the contrary, he has on every occasion stated that in his opinion *a drug will never be found which will completely destroy all the parasites in the body with one or two injections that will be without its dangers.* He has also frequently stated that the therapeutist can only do with his chemical knife what the surgeon does with his steel scalpel.

The entire process of manufacturing the substance is a most difficult one, as it must take place under nitrogen and absolutely without contact with the air, being a highly reduced product. It is kept in little glass tubes in a vacuum. In treating patients each tube must be opened and the contents either dissolved or suspended, as the case may be, and injected immediately.

Now as to the dose: We do not yet know how much can be given to a human being without causing injury. If the dose be calculated from the average animal dose (including the monkey), a human being could be given 5 or 6 gm. at one injection. It is, however, possible that a human being can stand less than even the most susceptible animal, and that half this quantity would be the maximum dose. Even should this prove to be the case, it is clear that the doses now being employed are very small ones (0.3 to 0.8 gm.). One gram has already been given in one intravenous injection without causing any severe reaction. A difference must of course be made between the subcutaneous and intramuscular injections, and the intravenous route; but the doses now being employed are about the same for both. The average doses given are about 0.6 gm. for women and 0.8 gm. for men by the two former, and 0.3 to 0.5 gm. by the last. There are some, however, who never use less than 1 gm. intramuscularly, and 0.8 gm. intravenously.

Under the head of technic it must be mentioned that the substance can be administered in two ways: either in a clear solution or in a neutral suspension. The clear solution of the drug is either acid or alkaline; both of these can cause considerable pain, but their effect is decidedly better than that of the suspension, which is, on the other hand, practically painless. The intravenous injection is not only painless, but in the hands of experienced workers is also without danger. The method of Iversen, recently published, by which he first gives an intravenous injection of 0.5 gm. and two days later an intramuscular injection of a suspension, with the idea of creating a storage of the drug, deserves serious consideration and promises to be the method chosen by careful workers in the future.

The great fear that this drug would have a bad effect on the optic nerve as do atoxyl and acetylatoxyl, experience has proved to be groundless. In about 12,000 cases that have been treated, not one report has been made of injury to the eyes. There have been a number of relapses, due to the smallness of the dose which was administered in the beginning of this work. A repetition of the injection, with a dose even larger than that first given, has also been found to be possible and causes the symptoms again to disappear completely.

It has been found by Hoppe that in the case of the intramuscular injection arsenic can be demonstrated in the urine and feces up to the tenth day, while in the case of the intravenous injection no arsenic can be found on the fourth day. One injection of the drug into infected animals causes the spirochetes to disappear completely within twenty-four hours, and in human beings within three days.

The rapidity of the cure in the primary stage depends on the character of the primary lesion. An erosive one heals completely within four or five days, whereas it requires eight to twenty days for an indurative chancre to be healed. The effects on the secondary symptoms are even better than on the primary. The eruptions disappear in some cases as if by magic, and throat lesions also heal within two or three days. Still more wonderful is the effect of the drug on tertiary lesions. This sounds paradoxical, but Ehrlich thinks it is due to the presence in the body of large quantities of antibodies which have had time to develop. Gummas disappear, and deep ulcers become clean and granulating within a very few days.

These results seem almost incredible, but they are demonstrated daily in the clinic of Wechselmann in the Virchow Krankenhaus, and in other clinics where the drug has been used. Whether dioxydiamidoarsenobenzol effects a permanent cure of syphilis by one injection in the majority of cases, only observations covering a long period of time can show. One thing, however, is now already certain: that it is not only superior to mercury and iodid of potash in the treatment of syphilis, but that it surpasses any known drug on account of the rapidity and apparent thoroughness of its action.

As I have stated above, acid or alkaline solutions can cause considerable pain, while the neutral suspension is practically painless; but its absorption and effect is slower. The amount of pain and discomfort following an injection varies with different patients. In general, it is said that women seem to suffer less than men, and babies apparently have no pain even from a strongly alkaline solution. It has generally been found that on the second or third day after injection, there is a slight rise of temperature which abates again within a few hours, and a slight tenderness at the site of the injection.

It should be mentioned again that "606" is a powerful medicinal agent, and it should be used only after the various technics have been thoroughly studied and mastered. It will never be a drug that can be used altogether in office practice like the frequent injections of the different mercurial salts; and the greatest caution must be exercised by those who use it, after it is given to the medical profession at large. An unattainable ideal would be to have the drug used only by trained genito-urinary specialists, just as a laparotomy is performed to-day only by a surgeon.

It is for this reason that Ehrlich has withheld the preparation from the general profession until many thousand cases have been recorded by competent and careful workers. The records of these cases will act as a bulwark against any future misuse of the drug by the incompetent.

Sandhofstrasse 44.

A CASE OF TORSION OF THE GREAT OMENTUM

W. W. RICHARDSON, M.D.
LOS ANGELES, CAL.

Although the case reports of torsion of the great omentum have greatly increased since the recognition of this condition has become more general, still it is of sufficient rarity to warrant the report of all cases, particularly of the intra-abdominal variety.

History.—R., male, aged 45, referred by Dr. W. V. C. Francis, with the following history: Appendectomy during an acute attack five years ago, with suppuration of the wound; since then the patient has had frequent attacks of abdominal pain of a colicky nature. July 22, 1910, an attack of unusual severity was followed by the formation of a tumor in the right iliac region which was tender to pressure. The temperature varied from normal to 101 F. The patient had not vomited. The bowels had moved daily. August 1, ten days after the commencement of his illness, the acute symptoms had subsided. He complained of little pain and appeared quite comfortable. The evening temperature was 100 F. The pulse was not accelerated. The abdominal walls were thick. There was no tympany nor rigidity. In the right iliac region, just lateral to a broad oblique scar, was a tumor about the size of a fist, slightly tender to touch and apparently superficial to the abdominal muscles. A diagnosis was made of strangulated epiplocele and operation suggested.

Operation and Findings.—The operation on August 3 revealed a mass of strangulated omentum about the size of a duck's egg, within a hernial sac, to which it was firmly adherent. The pedicle, two finger-breadths in thickness, was found continuous with a mass of matted and deeply congested omentum within the abdomen. This intra-abdominal mass was about the size of a goose-egg, firmly attached by old adhesions to the intestines, from which it was separated with difficulty. This mass was, in turn, attached by a pedicle the thickness of the thumb to the remainder of the great omentum. Both pedicles showed plainly the marks of torsion, and both omental masses the effects of venous obstruction. The strangulation was more intense in the intra-hernial mass, but in neither was it sufficient to cause gangrene. The patient probably would have recovered from this attack, as he had from previous less severe ones, as evidenced by the dense adhesions of both masses. Both omental masses were removed and the hernial opening closed by overlapping. Recovery was uneventful.

Adhering to the classification suggested in my previous article,[1] this case belongs to the group of intrahernial and intra-abdominal torsion about two points.

MYIASIS DERMATOSA DUE TO THE OX-WARBLE FLIES

ROBERT T. MILLER, JR., M.D.
PITTSBURG, PA.

Myiasis dermatosa, or infection of the skin with the larval stage of dipterous insects, is fairly common in the tropics though less so in temperate zones, the infection in man most commonly being due to the screw-worm (*Compsomyia macellaria*[2]) or to *Dermatobia hominis*.[3] The following case of human infection due to *Hypoderma lineata*, one of the ox-warble flies and a parasite of cattle almost exclusively, merits report because of its rarity.

Patient.—H. S., a white boy, aged 11, of Roanoke, Va., was admitted to Johns Hopkins Hospital, Baltimore, March 13, 1908, complaining of "swelling under the chin." His family and personal history are negative.

Present Illness.—In December, 1907, the boy noticed a small round lump just below the left knee; this lump was slightly red and very tender especially at night. About two days later the lump had disappeared from the original position and was found some three inches above the knee; the following day it was still higher on the thigh and during successive days it appeared at different points along a course up the abdomen, under the axilla, over the scapula, up the right side of the neck, irregularly about the scalp, finally passing back of the ear and to the submental region which it reached about two months after its first appearance; there it remained stationary, tenderness and pain having meantime greatly decreased. During January, 1908, there appeared in the left groin a second similar lump about the size of a finger-nail. This lump followed a course up the abdomen, under the right axilla and up to the back of the neck, reaching the occipital region in about three weeks, at which time it "came to a head"; the patient picked the scab off and pulled out a "white worm about one inch long and as thick as a darning-needle," alive and moving. These lumps were occasionally stationary but generally migrated three to four inches a day. The pain was not extreme but, with the tenderness and a stinging sensation, was more pronounced at night. At times the lumps would increase to the "size of his two fists" and become very painful.

Physical Examination.—In the submental region was a superficial fluctuating mass 2 cm. in diameter about which there was but little induration or inflammatory reaction. The cervical and axillary glands were generally palpable but small. Hemoglobin 75 per cent. White blood cells 7,700.

Differential count:

Polymorphonuclear neutrophils	54	per cent.
Polymorphonuclear eosinophils	8	per cent.
Mononuclears	30	per cent.
Transitional cells	1.5	per cent.
Unclassified cells	3.5	per cent.

Pulse and temperature normal. Urine negative.

March 13, under cocain anesthesia, the submental mass was incised, disclosing a small amount of finely granular detritus and a white larva lying in a cavity possibly 1 cm. in diameter and situated entirely in the skin. No motion was observed in the larva.

[3] Adams, J. Lee: Tropical Cutaneous Myiasis in Man, THE JOURNAL A. M. A., April 9, 1904, p. 947.

The larva was sent to Washington where, through the courtesy of Professor C. W. Stiles, it was identified as "the larva of *Hypoderma lineata* in the second stage."

The patient reported under date of June 24, 1910, that he was quite well and had had no further trouble.

While there are probably other cases recorded I have found in the accessible literature but one somewhat similar case[4] in which a small lump wandered irregularly over the chest wall, arm and back finally, at the end of five months, arriving on the cheek where it suppurated and was lanced discharging a larva subsequently identified at Washington as the larva of *Hypoderma bovis.* This case occurred in McKean County, Pa.

Hypoderma lineata and *Hypoderma bovis,* the ox-warble flies, are parasites of cattle. According to Curtice[5] the eggs of the former are deposited on the hair of the animal, carried by licking into the mouth and esophagus, where they adhere until the development of the larvæ which burrow through the tissues of the neck arriving at the skin, whence they travel in the skin itself to the back of the animal thus doing permanent injury to the hide. Folsom states that in six months of 1889 *Hypoderma lineata* alone was responsible for a loss of more than three and a quarter million dollars of which almost seven hundred thousand dollars represented injury to the hides.

In the present instance, however, the egg seems to have been deposited in the skin about the left knee, from which point the larva immediately began its migration through the skin without penetrating the deeper tissues. Neither in this case nor in Kane's case were there any constitutional symptoms, the sole inconveniences having been pain and local reaction caused by the burrowing of the larva.

I wish to express my thanks to Professor W. S. Halsted through whose courtesy this case is reported and to Dr. Thomas R. Boggs as well as to Professor C. W. Stiles for identification of the larva.

REVISED DIRECTIONS FOR MAKING AND USING THE WRIGHT BLOOD-STAIN *

JAMES HOMER WRIGHT, M.D., S.D.
BOSTON

Reports of unsatisfactory results obtained by some workers with the blood-staining fluid which I devised a number of years ago, and recent personal experience with it, have made clear to me that the directions for its preparation and application should be revised in order that certain faults in its working may be corrected or prevented. It is believed that the revised directions which are here given will enable the multitude of users of this reagent to obtain by it brilliant staining effects with more certainty and constancy than heretofore.

PREPARATION OF THE STAINING FLUID

To a 0.5 per cent. aqueous solution of sodium bicarbonate add methylene blue (B. X. or "medicinally pure") in the proportion of 1 gm. of the dye to each 100 c.c. of the solution. Heat the mixture in a steam sterilizer at 100 C. for one full hour, counting the time after the sterilizer has become thoroughly heated. *The mixture is to be contained in a flask, or flasks,* of such size and shape that it forms a layer not more than 6 cm. deep. After heating, allow the mixture to cool, placing the flask in cold water if desired, *and then filter it* to remove the precipitate which has formed in it. It should, when cold, have a deep purple-red color when viewed in a thin layer by transmitted yellowish artificial light. It does not show this color while it is warm.

To each 100 c.c. of the filtered mixture add 500 c.c. of a 0.1 per cent. aqueous solution of "yellowish, water-soluble" eosin and mix thoroughly. Collect the abundant precipitate which immediately appears on a filter. When the precipitate is dry, dissolve it in methylic alcohol (Merck's "reagent") in the proportion of 0.1 gm. to 60 c.c. of the alcohol. In order to facilitate solution, the precipitate is to be rubbed up with the alcohol in a porcelain dish or mortar with a spatula or pestle.

This alcoholic solution of the precipitate is the staining fluid. It should be kept in a well-stoppered bottle because of the volatility of the alcohol. If it becomes too concentrated by evaporation and thus stains too deeply, or forms a precipitate on the blood-smear, the addition of a suitable quantity of methylic alcohol will quickly correct such faults. It does not undergo any spontaneous change other than that of concentration by evaporation, according to my personal experience.

A most important fault encountered in the working of some samples of this fluid is that it fails to stain the red blood-corpuscles a yellow or orange color, but stains them a blue color which can not readily be removed by washing with water. This fault I have recently discovered to be due to a peculiarity of the eosin employed. It can be eliminated by using a proper "yellowish, water-soluble" eosin. Such an eosin I have obtained from R. L. Emerson, 739 Boylston Street, Boston.

APPLICATION OF THE STAINING FLUID TO BLOOD-FILMS

1. Cover the film with a noted quantity of the staining fluid by means of a medicine dropper.
2. After one minute add to the staining fluid on the film the same quantity of distilled water by means of the medicine dropper and allow the mixture to remain for two or three minutes, according to the intensity of the staining desired. A longer period of staining may produce a precipitate. Eosinophilic granules are best brought out by a short period of staining.

The quantity of the diluted fluid on the preparation should not be so large that some of it runs off.

3. Wash the preparation in water for thirty seconds or until the thinner portions of the film become yellow or pink in color.
4. Dry and mount in balsam.

Films more than a few hours old do not stain as well as fresh ones.

95 Mountfort Street.

Treatment of Diphtheria.—That our present method of treating diphtheria by antitoxic serum is defective is the contention of Sir Almroth E. Wright (*Proc. Roy. Soc. Med.,* October, 1910). Instead of adapting itself to the requirements of each individual case, it takes into consideration only the diphtheria bacillus and aims only at securing a high average of success. The method ignores the associated pathogenic organisms, such as the streptococcus, whose presence may involve almost as much danger to life as the diphtheria bacillus itself. The laboratory bacteriologist aims to produce a serum that will conform to accepted laboratory tests and achieve the highest possible antitoxic potency, leaving out of sight the fact that a diphtheric infection is something more than an intoxication by diphtheric poison.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1910," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

Articles which have already been mentioned in detail in THE JOURNAL are as follows:

THEOPHYLLIN SODIO-ACETATE — Theophyllinæ sodioacetas—Theophyllin sodium acetate $C_7H_7N_4O_3Na+CH_3COONa+H_2O$, is a double salt of sodium acetate and 1, 3-dimethylxanthine-sodium (theophyllin sodium).

It is a white crystalline powder, containing about 60 per cent. of anhydrous theophyllin. It dissolves in about 20 parts of water at 25° C. (77° F.), but is insoluble in alcohol or ether.

Actions and Uses.—It has the diuretic properties of theophyllin reinforced by the diuretic action of sodium acetate, and being more soluble, it is claimed to be more readily absorbed and to be better tolerated than theophyllin.

It is said to be useful in cardiac affections, nephritis, dropsy, etc.

Dosage.—0.2 to 0.35 Gm. (3 to 5 grains), best given after meals.

Proprietary Preparation:

ACET-THEOPHYLLIN-SODIUM—Acet-Theophyllin-Sodium is a name applied to theophyllin sodio-acetate.

Manufactured by C. F. Boehringer & Soehne, Mannheim, Germany (Merck & Co., New York). U. S. patent Nos. 667,381 (Feb. 5, 1901; expires 1918); 757,328, 757,329 (April 12, 1904; expires 1921).

PHARMACEUTICAL PREPARATIONS ACCEPTED FOR N. N. R.

The following dosage forms of accepted proprietary articles have been accepted for N.N.R.:

Syrup Thiocol Roche.—A syrup containing thiocol 10.5 gm. in 100 c.c. (6 grains in a fluidram).

Therapeutics

THYROID

The thyroid is a ductless gland that has so many physiologic activities that it belongs in a class by itself. The desiccated thyroid glands of the Pharmacopeia are offered as a yellow, amorphous powder, having but slight odor or taste, and being but partially soluble in water. This powder is prepared from the thyroid glands of the sheep, and one part of this official powder should represent about five parts of the fresh gland.

Around the thyroid are small gland structures called parathyroids, and in early experiments with animals in which the thyroids were removed more or less of these parathyroids were also removed; consequently, many of the symptoms described as due to thyroid extirpation were really due to the combined removal of both thyroid and parathyroids. It has since been positively determined that these two gland structures have very different physiologic activities and that both are necessary for the health and welfare of the individual.

In 1895, Schiff first showed that dogs could not live when these glands had been totally removed, but would live if part of the thyroid, and, therefore, some parathyroids, were left. It has since been shown that the convulsions are really due to removal of the parathyroids. The adult human thyroid varies considerably in size, depending on the age of the individual, on the sex, and on the locality in which the individual resides. It may vary in weight from 20 to 60 grams. In the female, the gland enlarges during menstruation and pregnancy, and much more frequently becomes diseased (either simply enlarged or atrophied, or hypersecretes or hyposecretes) in the female than in the male. In both sexes the gland more or less atrophies after the age of 50. It has been proved that the thyroid glands are larger in individuals residing at the seashore, and larger in certain regions than in other regions, this being due, possibly, to the character of the water drunk or to the different constituents of the atmosphere. At the seashore there is more iodin in the air, and iodin in any form is a stimulant to the thyroid gland.

Exactly how the thyroid carries on its various activities has not been discovered. The colloid secretion is an important part of its function, and although not directly utilized, it may be used by the gland as a storehouse for the substances that it needs in performing its other work. If it is in large amount the gland is pathologic, and in very large amount a cystic goiter is the condition. If the thyroid, as a whole, underfunctionates, various symptoms and conditions develop, which will be explained later, and if it becomes actually diseased and its secretion becomes greatly diminished or even nil, *cretinism* and *myxedema* are the consequences. If, on the other hand, its normal activities are increased, various symptoms develop, which will also later be described, and if the secretion is excessive the conditions of Graves' thyroid disease, *exophthalmic goiter,* is the consequence. It is certainly readily conceivable and seems to be true from clinical experience that certain activities of the thyroid can be perfect while other of its activities are impaired, and varying symptoms are the results of such physiologic changes. It is probable that certain activities of the thyroid may be permanently increased, diminished, or absent, and yet other activities be normal, and many unexplained clinical conditions follow.

If the activity of this gland, as is true of all the internal secreting glands, is greatly impaired, other glands may take up, or assume, or attempt to do part of the thyroid's work. This seems to be especially true of the hypophysis cerebri when the thyroid is diseased. The opposite is also true, that the thyroid becomes disturbed in pituitary disease.

The physiologic functions of the thyroid may be summed up as follows: Its perfect secretion is necessary to the growth of the body in childhood; it is necessary for normal mental ability; it is necessary for proper nitrogenous metabolism; it is necessary for the proper development and distribution of fat; it is necessary for the proper development of the genital organs and their secretions, for normal menstruation and normal pregnancy, and to prevent nitrogenous toxemias.

If the thyroid is absent or its secretion is insufficient in the child, the child becomes a *cretin,* which means that it shows short, stunted growth; is fat and flabby; has a round, full, expressionless face; has a sluggish mentation; and is a semi-idiot. If the gland is extirpated or its secretion becomes enormously diminished or absent, *myxedema* is the result, a condition occurring most frequently in women after the menopause, in which there is an enormous putting on of weight, mostly fat; a puffy condition of the skin, due to an excessive amount of mucin in its interstices; a gradually diminishing mental ability; the same condition of expressionless, fat, rounded face as seen in the cretin; soon circulatory debility; various maldigestions; and kidney insufficiency.

If any individual does not have normal thyroid secretion his mental ability is impaired, and the administration of thyroid substance will often improve the condition. Disease of the thyroid may even be the cause of some melancholic insanities, and such insanities are sometimes improved by the administration of thyroid.

The administration of thyroid will increase nitrogenous metabolism and increase nitrogenous waste, as shown by the excretion of nitrogen in the urine. When the nitrogenous metabolism is impaired and not sufficient nitrogen is excreted, the feeding of thyroid will increase the nitrogen excreted and improve the general condition. Also in nitrogenous toxemias as occurs in puerperal eclampsia and in uremia from kidney insufficiency, thyroid will often prevent the cerebral toxemia and may aid in curing the condition.

If the thyroid is insufficient in its secretion and not sufficiently diminished to cause myxedema, the weight is increased by large deposits of fat. This is noticed when the thyroid normally diminishes its secretion after the age of 45 or 50, when most individuals put on weight, especially women. It is also noticeable at other ages, especially in women, if the menstruation unaccountably ceases. This deposit of fat is the marked feature of *adiposis dolorosa,* and all of these patients are benefited, the fat is diminished and the weight is decreased by administration of thyroid. *Per contra,* if the thyroid secretion is excessive, as in Graves' disease, the patient loses weight and the fat is diminished.

The thyroid should be fully developed at puberty, and it seems to be one of the predisposing causes of the beginning of menstruation in girls. If the thyroid is not developed and normally secreting the genital organs do not develop or properly functionate. If it does not secrete properly amenorrhea is the consequence. If it over-secretes, menorrhagia is the result. It normally enlarges a few days before the menstrual epoch, and with this hyperemia comes all the exciting and nervous disturbances which increased secretion of the thyroid can cause. The anemic condition termed *chlorosis* bears some close relation to disturbance of the thyroid, and the administration of thyroid is as efficient in correcting chlorosis and in causing normal menstruation (and often more efficient) as iron. The healthy enlargement and increased secretion of the thyroid during *pregnancy* is essential for the proper growth of the fetus and the prevention of nitrogenous toxemias from the double metabolism of both mother and child. If the thyroid does not diminish its secretion after the *menopause,* symptoms of its activity are troublesomely evident, viz., hot flashes and vasomotor dilatation, nervousness, breathlessness, sleeplessness, and palpitation.

The less the ability of the thyroid to functionate normally the less the protein that should be taken into the system; also, much meat tends to keep up the hyperactivity of the thyroid in Graves' disease, the nitrogen seeming to stimulate the gland. Certain it is, such patients do better without meat. On the other hand, in under-secretion of the thyroid as generally seen after the age of 60, the patient demands and requires less and less meat, and is doubtless better off without much meat.

The tendency of the human being from 45 upward gradually to have an increase of blood-pressure, and gradually to develop a tendency to connective tissue formations in various parts of the body, is *pari passu* with the diminished thyroid secretion. Thyroid secretion has a constant activity in lowering blood-pressure, and the administration of thyroid will do the same. If the thyroid is removed from young animals they do not grow, become stupid, have a lower temperature, and unless thyroid is administered, sooner or later die. If an older animal has the thyroid removed, the mental condition becomes sluggish, the muscles become weak, the skin thickens, the hair may fall out, he may or may not lose weight, the temperature is diminished, circulation is impaired, anemia may develop, and if the animal lives long enough sclerosis of the larger vessels may occur.

It has been estimated that there are sufficient blood-vessels passing through the thyroid to allow the whole blood of the body to pass through the gland at least once an hour. If the circulation of the thyroid is enormously increased, as it is in the dilated condition of the blood-vessels in Graves' disease, the blood could go through the gland perhaps twice as frequently as normal, consequently the blood would contain twice as much thyroid secretion as normal. This fact alone would be a cause of the thyroid intoxication and symptoms of exophthalmic goiter.

The colloid secretion consists of two albuminous bodies, and there is a small amount of phosphorus and a nucleoalbumin in the gland. In 1895, Baumann discovered iodin in the colloid secretion and prepared a substance which he called iodothyrin, which is an iodin protein combination which it was supposed would represent the activity of the gland, but has been proved not to act like thyroid substance. While the colloid substance is the chief seat of the iodin content, the thyreoalbumin of the follicular cells has been shown to contain the element (Aeschbacher, *Berl. klin. Wchnschr.*, Feb 12, 1906).

The administration of thyroid will increase the nitrogen, sodium chlorid, and phosphorus output in the urine, while a diminished secretion of thyroid may decrease the output of nitrogen and phosphorus. The thyroid is probably the only organ of the body that contains iodin, and there is more iodin in the thyroids of individuals living at the seashore or where goiter is endemic than in other regions. There is also more iodin in the thyroid during its period of greatest activity, viz., from 15 to 40. The activity of the thyroid is diminished after perhaps its primary stimulation, in *infectious diseases, tuberculosis*, and *chronic alcoholism*, and the iodin is also decreased in these conditions. *Circulatory disturbances* that would cause chronic passive congestion seem to diminish the activity of the thyroid and the amount of iodin it contains. *Carcinoma* has been shown to cause an increased amount of iodin in the thyroid. The administration of iodin is a stimulant to the thyroid gland and will increase the iodin content to a certain amount, and then it is increased no more. This shows that there is no necessity for enormous doses of iodid since its best action is perhaps in stimulation of the thyroid and increasing its iodin content. *Syphilis* and the prolonged administration of mercury seem to diminish the secretion of the thyroid and may cause its early atrophy, hence perhaps the cause of the frequent connective tissue sclerosis and arteriosclerosis that occurs after this disease and its cure by mercury. *Chronic lead poisoning* will cause the thyroid secretion to be diminished. Ordinary circulatory stimulation, especially with such drugs as caffein, tea and coffee, will stimulate the gland to increased activity. So do single doses of alcohol; but not so chronic alcoholism. Arsenic is a stimulant to the thyroid secretion; phosphorus is a stimulant to the thyroid. The glycerophosphates seem to diminish thyroid secretion. The thyroid seems to regulate the calcium metabolism, and it has seemed that thyroid feeding was valuable in the slow deposit of callus about a fracture. Also, the lack of bone growth in the cretin child is so stimulated by thyroid as to suggest an action on calcium or phosphate metabolism.

Various investigators, notably Hunt and Marine, have shown that iodin is necessary for the normal thyroid activity and is an index of the physiologic value of the thyroid secretion (thyreoglobulin). As to whether the administration of iodin will increase the activity of the thyroid gland depends on the gland's ability to store it and not on the method of administration. In other words, the greater the glandular hyperplasia the greater the amount of iodin it will store. The percentage of iodin which the thyroid may contain varies, and the thyroid gland substance obtained from various sources varies greatly in its iodin content, and consequently greatly in thyroid activity.

Reid Hunt (The Journal, October 19, 1907) has shown that the iodin of the thyroid glands of animals not only varies in different animals, but from time to time in the same animal, and varies with the character of the food taken. He has found that while thyroid substance that does not contain iodin is not absolutely inactive, it has a low degree of activity. He has shown that animals are more susceptible to morphin if their thyroids are normally active or if they are given active iodin-containing thyroid stuff. Hence this bears out the clinical findings that patients with Graves' disease often do not bear morphin well, and, as he suggests, this may be the reason that they do not bear ether and chloroform well, their susceptibility to narcotics being perhaps increased by the increased thyroid secretion. As the activity of the thyroid substance depends so largely on iodin, and as the iodin content varies so greatly in the different preparations on the market, it may be well when thyroid treatment is indicated to administer conjointly a small amount of iodin, perhaps best as sodium iodid.

The activity of thyroid, when administered, seems to be parallel with its iodin content, and frequently hyperplastic thyroids will become smaller in size under the administration of any iodin-containing substance. Marine and Lenhart seem to have shown (*Arch. Int. Med.*, November, 1909) that iodin in sufficient amount will prevent enlargement of the thyroid or hyperplasia of the thyroid. This seems negatively to show that goiter develops on account of insufficient iodin, and that the regions where goiter develops are regions where iodin is deficient in the water and air. It seems proved that during the stages of enlargement of the thyroid the iodin is deficient. This does not always of necessity mean that iodin is absent or deficient in the air or water or foods taken, but that for some reason or other it is not assimilated and, therefore, that there is a starvation of iodin.

Although boiling the water or changing the water seems to decrease goiter in some instances, this by no means is an argument absolutely in favor of the infectious origin of goiter. Boiling the water might cause such a deposit or chemical change in the substances in the water as to remove a chemical substance that was antagonistic to the iodin normally taken into the body, or that caused the formation of a compound which would prevent the iodin from being normally absorbed or normally utilized by the thyroid.

Marine and Lenhart report the following findings: The iodin content of the thyroid gland varies inversely with the degree of active hyperplasia; partial removal of the thyroid is normally followed by a compensatory hyperplasia of the remaining portion; iodin starvation increases the amount of the hyperplasia; the administration of iodin causes the hyperplasias of the thyroids of all animals to revert to the colloid state; in whatever form iodin enters the organism, it is stored in the thyroid, and that regardless of how much there is in other tissues; the rapidity of accumulation and the amount of iodin thus taken up by the thyroid depends on its size and the degree of active hyperplasia; and the nitrogen excretion seems to bear a distinct relation to the amount of iodin in organic combination in the system.

It has been shown that thyroid substance is the most active of any iodin-carrying compound as a stimulant to thyroid gland activity. Clinically it has been found that iodin, even in small doses, administered as an iodid, when there is hyperactivity of the thyroid, has caused the same disturbance that desiccated thyroid has caused, when administered under the same conditions. This is not true in patients who have normal thyroids. In other words, iodin has no noticeable effect clinically on the activity of the thyroid in normal individuals, while thyroid feeding will cause its physiologic action in such individuals.

It seems to be a fact that in exophthalmic goiter the thyroid is abnormal either by hypersecreting or by having a perverted secretion, and this seems to be a cause of the disease. The active enlargement may be a compensatory condition caused by a disturbance of nutrition. It seems positively demonstrated and known that hyperplasia of the thyroid occurs at some period in every case of exophthalmic goiter, and the severity of a case of exophthalmic goiter generally varies directly with the degree of colloid and coincident lymphoid hyperplasia. It is stated that the operative mortality of exophthalmic goiter is greater in these instances than in those in which there is marked hyperplasia and a low iodin content. Also, the greater the lymphoid hyperplasia of other glands apparently the greater the mortality. It seems, then, in exophthalmic goiter that the gland is hyperactive, and that its hyperactivity is compensatory for some deficiency in the organism.

Marine claims that the hypersecretion of the thyroid in exophthalmic goiter is a quantitative increase, but really a deficient qualitative secretion, and that the final stage of every case of exophthalmic goiter, if the patients do not soon die, will be myxedema or relative recovery; in other words, under-secretion of the gland. Myxedema and cretinism represent the final stage of a prolonged deficient secretion.

It has been noted that the thyroids of new-born animals do not contain iodin. It has also been noted that when part of the thyroid gland is removed the other part will show an increased amount of iodin. Hunt states, too, that an exclusive meat diet leads to a diminution of the amount of iodin in the thyroid. It has also been shown that if the iodin content of the thyroid is diminished and the thyroglobulin consequently diminished, the thyroid tends to hypertrophy, and a cystic goiter generally shows a diminution of iodin.

Hunt says that the normal swelling of the thyroid gland during menstruation and pregnancy is more marked in goitrous regions than elsewhere, and in these places, he says, there is less iodin in the thyroid. Consequently, the inference should be drawn that a simple hyperplastic thyroid without a great increase in colloid will become normal in size by the administration of a small amount of iodin, sometimes a few doses being sufficient, each perhaps not more than 0.20 gram (3 grains). If, however, the condition was that of marked Graves' disease, iodin would perhaps increase the activity and do no harm.

Either thyroid or iodin may increase the menstrual flow as has often been proved clinically, while large doses of an iodid may cause its cessation.

Hunt has found that the feeding of potassium iodid to animals has diminished their resistance to morphin as does thyroid feeding, because it stimulates the thyroid gland. The stimulation, however, with any iodin soon reaches its limit, as Hunt says, probably when all the thyreoglobulin has its full iodin content. The adult thyroid contains about 0.004 gram of iodin.

Thyroid has no action locally, but acts only after absorption. Its preparations are probably broken up in the stomach into various proteid combinations, but the gastro-intestinal secretions do not impair its activity. If taken on an empty stomach, if in at all large dose, it causes some nausea. Its first action is as a vasodilator, and the blood-pressure is somewhat lowered. While very large doses quickly absorbed might cause cardiac depression and cerebral excitation, such symptoms from one dose are rarely seen. It is only from small doses continued for some time that its physiologic action is evident. The symptoms that it causes when its action is thoroughly in evidence are nervous excitation, restlessness, sleeplessness, palpitation, a feeling of general warmth by vasodilatation, sweating, loss of weight, perhaps loss of appetite, diuresis, and an increase of nitrogen and phosphorus (P_2O_5) in the urine. Such an action from thyroid represents intoxication from it, and is undesirable, and should be avoided. If such action occurs the drug should be given in smaller dose, or perhaps not administered at all.

The iodothyrin of Baumann does not represent the whole of the activities of the thyroid, consequently thyroidectomized animals can not be kept alive or in health by feeding iodothyrin as they can by feeding thyroid substance. From the thyroid have been obtained a nucleoproteid which contains phosphorus and a globulin which contains iodin. This last is termed thyroglobulin, and Oswald (*Münch. med. Wchnschr.*, Aug. 15, 1897) says that it is the iodin globulin that increases nitrogenous elimination, while the nucleoproteids, phosphorus stuff, do not. The iodin of this thyroglobulin varies in amount, while the elements of carbon, nitrogen, oxygen, hydrogen, and sulphur remain constant. If iodid of potassium is fed to an animal before its thyroid is removed the colloid will contain more iodin than if such is not administered. Oswald thinks that, when the thyroglobulin which circulates in the blood is metabolized and broken up, the iodin is not entirely lost, but again returns to the thyroid and may again be used. Investigators seem to have proved that to increase nitrogenous metabolism the thyroglobulin of the thyroid substance fed must contain iodin. They also seem to show that it is the iodin combination that gives the thyroid its antitoxic power. In other words, a thyroid short on iodin does not allow normal nitrogenous metabolism to take place in the body and is not normally antagonistic to either infections or to the toxins of metabolism.

While iodin has been found in the parathyroid glands, it has not been determined that it is constant in these glands. It is possible that the parathyroids may assist in thyroid work if the latter is diseased, and it has been shown that the parathyroids hypertrophy if the thyroid is in large part removed. The same is true of the hypophysis cerebri. The reverse is also true; if the hypophysis is diseased or the parathyroids in part removed, the thyroid secretion seems to be disturbed.

The antitoxic importance of the thyroid secretion is shown by the fact that the urine of animals deprived of their thyroids is much more toxic than of normal.

Directly or indirectly, the thyroid also seems to have some control over the development of connective tissue, as when the thyroid secretion is diminished from any cause or this occurs normally at the age of the thyroid's atrophy (viz., after 45) the connective tissue may increase in various parts of the body.

The apparent size of the thyroid gland is no criterion as to the amount of normal secretion it is furnishing. It may be large and be producing much less than the proper amount of normal secretion, and it may be apparently small or not at all enlarged and be producing a much increased amount of secretion. It is positive that an increased secretion from this gland stimulates and irritates the brain and that a diminished secretion causes mental apathy and mental sluggishness, but whether an increased secretion or abnormal secretion can excite a brain to a mania, or an under-secretion can cause cerebral degeneration, has not been determined.

CHRONIC ANTIMONY POISONING AMONG TYPESETTERS

The occupational diseases form a group of disorders which have not received the attention which their importance merits. Too often it happens that the physician is satisfied with an indefinite or incomplete statement from the patient as to the nature of his vocation or calling. A fact of prime etiologic significance is thus lost and the patient is the sufferer in more than one particular. In considering the common occupational diseases there is also the danger of assuming that atypical symptoms are unusual manifestations of the suspected cause. Further inquiry might elicit valuble clues.

This is well illustrated by the recent studies of Strumpf and Zabel,[1] who have been in a position to follow carefully the physical condition of a large number of typesetters in Strassburg, Germany. One thing which impressed them was the rarity of typical cases of lead-poisoning. They observed, however, with great frequency, a clinical syndrome characterized by a fatigued expression, nervousness, irritability, insomnia, exhaustion especially in the morning hours, vertigo, headache, particularly in the frontal and occipital regions, general or local muscular pains, neuralgic pains in the extremities, nausea and vomiting, and constipation. Mild, moderately severe and severe cases were encountered. The authors find evidence in the literature that this symptom-complex has been looked on as a manifestation of chronic lead-poisoning. The patients showed no elevation of blood-pressure, which, as Krehl has shown, is so common in plumbism from spasm of the arterial walls; the erythrocytes had no basophilic granules; and leukocytosis was lacking. Nor did the urine show traces of albumin or bile. On the contrary, the red count was almost or quite normal even in the severe cases with an absence of basophilic granules and there was leukopenia with eosinophilia between 10 and 25 per cent. (Typesetters without symptoms possessed as high as 9 per cent. eosinophils.) The urine was normal and likewise the blood-pressure.

Since the facts observed suggested no connection with plumbism, Strumpf and Zabel visited the presses where the men were employed, and found, on inquiry, that a mixture containing lead (70 to 80 per cent.), tin (5 per cent.), and antimony (15 to 20 per cent.) was used in covering the type. As tin is without importance toxicologically, their attention was directed to antimony. Rabbits were subjected to chronic antimony poisoning and soon exhibited a well-marked reduction in number of the white cells with increase in the eosinophils up to 25 per cent. The feces of the poisoned rabbits yielded an antimony mirror with Marsh's test.

From this experimental evidence, corroborating their clinical blood-findings as it did, Strumpf and Zabel felt that their patients had been suffering from chronic antimonial poisoning. Since they obtained a positive Marsh test for antimony from the stools of two patients, there can be little doubt that their surmise is correct.

Absence from work for two to three weeks, with exercise in the open air and a milk diet, sufficed usually to restore the patients' health. Thus a new danger to typesetters working with antimonial compounds is brought to light and a distinct contribution added to the growing subject of occupational diseases.

INSANITY IN THE MILITARY SERVICE

Among the medical officers of the Army and of the Navy lately there has been a remarkable growth of interest in psychiatry. In other countries, notably France and Germany, the relation of insanity to conditions of military service has received considerable attention and an extensive literature on the subject is available, but till now the matter has been almost ignored in the United States. The interest which is now being shown in so many different ways is due in part to the influence of the clinical instruction given by Dr. William A. White to the student-officers of the service schools at Washington.

The opportunities for obtaining practical work in psychiatry, even at the best medical schools, are pitifully meager, and it is not at all surprising that the adequate presentation of the subject under such conditions as the Government Hospital for the Insane affords should enlist the attention and, in many cases, the enthusiasm, of the young officers and of the older ones who are assigned from time to time for courses of instruction at the Army and Navy medical schools. One result of the newly awakened interest is that already valuable observations on insanity in the military service are being published.

Some observations of especial interest are those of Passed Assistant-Surgeon Heber Butts[1] and Captain Robert L. Richards, Medical Corps U. S. Army.[2] Dr. Butts gives interesting statistics regarding the 528 officers and men who have been admitted to the Government Hospital for the Insane at Washington from the active lists of the Navy and Marine Corps during the period from Jan. 1, 1899, to June 1, 1910. He comments on some of the relations of race, rank or rating, types of mental disease and etiologic factors in this group of cases. Some of the observations agree with the facts ascertained by statistical studies of admissions to state hospitals for the insane, but there are some interesting variations which must reflect the effects of conditions of military service and which must have great interest for military medical officers when they have been studied at greater length.

---

[1] Strumpf and Zabel: Ztschr. f. exper. Path. u. Pharmakol., 1910, lxiii, 242

[1] United States Naval Medical Bulletin, October, 1910; *abstracted* in The Journal, Oct. 22, 1910, p. 1501.

[2] Am. Jour. Insanity, July, 1910; abstracted at length in The Journal, Sept. 3, 1910, p. 875.

In spite of a high prevalence of syphilitic infection among the enlisted men of the Navy, only 5.11 per cent. of all admissions to the hospital were for general paresis. In the New York state hospitals for the insane, paretics form about 19 per cent. of all male first admissions. It is safe to conclude that by far the larger proportion of cases of paresis in sailors occur after they have served their enlistments and left the Navy. The government suffers from the large number of men incapacitated from duty on account of syphilis, but the communities in which the discharged seamen take up their residences subsequently bear the burden of supporting the paretics who find their way into state institutions a dozen years after their careers in the Navy have closed.

The large proportion of cases of dementia præcox, 33.52 per cent. of all admissions in this group, is largely accounted for by the low ratio of paretics and by the youth of the men admitted, the number of cases of involutional psychoses and of senile deterioration, which form so large a part of all admissions to state hospitals, being for these reasons much less.

By far the most important phase of insanity in the military forces is, as Dr. Butts points out, its relation to recruiting. He shows that the expense to the government which enlistment of an insane man occasions, the detriment to the efficiency of the service involved by his presence and the difficulty in deciding whether or not he shall be given the benefits which come to those who have received their disability in "line of duty," all combine to make the determination of the mental status of the applicant for enlistment of the highest importance. In forty-four cases, or nearly 9 per cent. of all in the group considered, mental disease became apparent within thirty days from the time of enlistment, and synopses of typical cases are given in which there was plenty of evidence at the time of enlistment that the men were insane or mentally inferior. This seems to indicate that the present system of examination is inadequate to exclude with a conspicuous degree of success actually or potentially insane men from the Navy and Marine Corps. It is to be remembered that the Navy is particularly exposed to this danger, for, besides the men who enlist for reasons which are actually the outgrowth of delusions, a considerable number enlist for the purpose of escaping from an environment in which they have failed to "make good," and not a few for the purpose of being sent to remote places where they hope to escape the consequences of misdeeds. Among men of this class many are constitutionally inferior and some are insane.

To guard against enlisting such men is an important duty of medical officers. Dr. Butts suggests the advisability of devising some means of giving a practical mental examination, and that accepted candidates be required to serve a six months' period of probation in order to determine their mental status and their aptitude for the service and for the rating in which they have enlisted. We are inclined to think that the factor which will have the most influence in selecting recruits with a smaller percentage of insane and mentally defective men will prove to be the successive classes of young medical officers coming into active duty with practical knowledge of the fundamentals of clinical psychiatry. When a considerable number of the earnest and well-trained young medical men who are at present entering the Navy add to their professional training in other directions such a knowledge of mental diseases as can be obtained at St. Elizabeth's, there will be fewer insane men enlisted, especially of the type of which Dr. Butts gives examples. This work is of so much practical importance that it seems that even more attention might be given it in the courses of instruction at the service medical schools at Washington.

AMERICAN JOURNAL OF DISEASES OF CHILDREN

The first number of the *American Journal of Diseases of Children,* the new periodical to be published by the American Medical Association, will appear in January, 1911. This journal is established at the request of a large number of the leading pediatricians of the country. At the St. Louis session, the Board of Trustees recommended to the House of Delegates that such a journal be established and the recommendation was adopted. At its meeting in June the board decided that the publication should begin in January, and that there should be an editorial board of six, as in the case of the *Archives of Internal Medicine.* At the October meeting the Trustees selected, from those recommended by a committee of pediatricians previously appointed for the purpose, the following Editorial Board: William Fitch Cheney, San Francisco; Frank Spooner Churchill, Chicago; Edwin E. Graham, Philadelphia; John Howland, New York City; Abraham Jacobi, New York City; John Lovett Morse, Boston.

The journal will be of a high order. The character of the members of the editorial board is a guarantee that the articles presented will be creditable to American pediatrics. The interests of the general practitioner are to be kept especially in view, inasmuch as the treatment of children forms a large portion of his work.

The more technical articles of the specialist and the research worker of course will have the prominent place in the journal. Among the contributors to the first number will be Abt, Bevan, Dunn, Fetterolf, Gittings, Hamill and Blackfan, and Jacobi will write an introductory editorial. In addition, there will be comments on live topics in pediatrics, as well as abstracts of current pediatric literature by pediatrists who know what is of real interest.

From a mechanical point of view—paper, printing, illustrations, etc.—the *American Journal of Diseases of Children* will be equal to the *Archives of Internal Medicine*, which means that it will be equal, if not superior, to any other scientific periodical in this or in any other country.

It is needless to say that the new journal is not published as a money-making proposition. It is expected to pay its way; that is all. The Association is now peculiarly well equipped to publish high-class medical periodicals—better even than the majority of the large printing establishments. When the transfer is made to its new building this month, the printing establishment of the American Medical Association will be one of the most complete of the kind anywhere, making it possible to produce the best work in the most economical manner. As a matter of fact, no private individual could produce such a journal as the *Archives of Internal Medicine* at its subscription price, unless he did it for purely altruistic purposes, disregarding business principles. Likewise, it would be impossible, at the proposed subscription price, for a private individual to publish without loss a journal such as the *American Journal of Diseases of Children* will be.

Our European confrères are being led to acknowledge that American medicine, in all its branches, is forging to the front. In fact, they are forced to concede that in some branches we excel. They will soon have to admit that our current periodical literature is also setting a standard. It is intended that the *American Journal of Diseases of Children* shall be a credit to American pediatrics, and we bespeak for it the hearty support of the profession. An announcement, with the subscription price, appears[1] in the advertising pages of this issue.

Current Comment

MEDICAL EDUCATION IN COLORADO

Early in the present year an agreement was made to merge the Denver and Gross College of Medicine, of Denver, with the University of Colorado School of Medicine, the latter school being located at Boulder. By the terms of the merger the work of the first two years would be continued at Boulder, but the work of the clinical years would be conducted at Denver, where better hospital facilities were obtainable. Before such an arrangement could be made, however, it was necessary to secure an amendment to the state constitution, which specifically stated that all the work of the state university should be conducted in Boulder. An amendment, therefore, providing that "all but the first two years of the departments of medicine, dentistry and pharmacy" *might be conducted at Denver*, was submitted to the people at the recent election. Incidentally, perhaps this is the first time that the people individually have had the opportunity to express an opinion in regard to medical education. The result shows that, at least in Colorado, they are in favor of better standards, for the amendment was adopted by a large majority. This amendment permits the merger between the two medical schools to be completed Jan. 1, 1911, according to the terms of the agreement. Thereafter, Colorado will have but one medical school and that will be conducted by the University of Colorado. Two years of collegiate work are required as the minimum of preliminary education, which standard has been adopted also by the Colorado Board of Medical Examiners. Prospects are good, therefore, for the rapid improvement of medical education in Colorado.

FILTRATION OF WATER-SUPPLIES

A recent number of the *South African Journal of Science* contains a paper by Dr. D. M. Tomory on methods of water purification, which indicates that South Africa is alive to the important question of pure water-supplies. The Modder River, which supplies Bloemfontein, cannot be effectively purified by sand filters, since they become clogged by the clay held in suspension. A remarkable improvement was obtained by precipitating with lime and permanganate and filtering rapidly through a mechanical filter, which caused a reduction of the deaths from typhoid fever from 83 per 10,000 in 1896 to 2.75 per 10,000 in 1908. On account of the necessity of increasing the capacity of the plant, the authorities made a tour of inspection in Europe and America to obtain ideas on water purification. In the northern United States and in England, sand filtration was generally found efficient, but in the southern United States and in Egypt conditions analogous to those in South Africa were found, which had been met in similar ways, by precipitation and mechanical filtrations. Tomory concludes that the extraordinary rapidity of mechanical filtration is not accompanied by special risk of pollution when the process is used intelligently in connection with chemical precipitation processes, and that, in cases of non-settling waters which can be purified only by such precipitation, rapid filtration is decidedly preferable as at once more efficient and economical.

HEALTH IN THE TROPICS

The remarkable success of Colonel Gorgas and his co-workers in doing away with the excessive prevalence of infectious diseases in the Canal Zone has been referred to previously.[1] The direct effect of tropical conditions on the human organism cannot, however, be viewed with as much satisfaction as is entertained by Colonel Gorgas if we accept the opinion of an editorial writer in the June *Bulletin of the Manila Medical Society*. This writer presents a rather depressing view of the effect on health of prolonged and permanent residence in tropical countries. He pictures vividly the steady decline in energy and efficiency in those from temperate climates who take up their residence in the Philippines. He remarks gloomily that if one "is so constituted that he can accept this lowered energy efficiency as a conservation process and regulate his life accordingly" he "usually gets along fairly well for a number of years and finally reaches a condition of general sluggishness of mind and body which is characteristic of the majority of those whose lives are spent in tropic climates." In other words, life in the tropics is simply life on a lower plane of accomplishment. The condition is not one of disease, but simply *normal life governed by a different measure of efficiency.* This writer is especially severe on foreigners from temperate climates who attempt to rear children under tropical conditions.

RED CROSS SEALS—A WARNING

Last week we called attention to the American National Red Cross seals, and heartily endorsed this method of raising funds for a splendid cause. The American National Red Cross, of course, has no control over the idea, and cannot prevent others from adopting it. We probably should have given this word of caution last week, so that physicians would not be misled into endorsing some imitation of the idea without thorough investigation. During the last few days we have received letters from physicians showing that another stamp is being promoted, and at least one physician has been misled. This bears the label of the "National Antituberculosis Association, Chicago," has in its center the word "hope" in white on an orange background, and, instead of the red cross, has the ordinary cross in black. The American National Red Cross has appointed the Illinois State Association for the Prevention of Tuberculosis as its sole state agent for Illinois for the distribution of the Red Cross seals. We have consulted the officers of this organization, who state that this "National Antituberculosis Association, Chicago," is not recognized by them. From the officers of the Chicago Tuberculosis Institute we learn that the organization issuing this black cross stamp has not made known how its funds would be disposed of, and that they do not recommend it to the public for support. It is reported that those who retail these particular stamps make a profit[1] of 40 cents on the dollar; those who sell the American National Red Cross seals do it for altruistic purposes. We again urge physicians to cooperate heartily with the American National Red Cross and the branches of the National Association for the Study and Prevention of Tuberculosis, in their work, and also to discountenance any unauthorized scheme that may mislead the public.

Medical News

CALIFORNIA

Personal.—Dr. S. M. Augustine, San Rafael, has donated $2,000, bequeathed by the will of the late William Patton, toward the construction of a playground for school children of the city.——Dr. Pauline S. Nusbaumer has been appointed city bacteriologist of Oakland.

Offenders Against the Law.—Robert Thompson, San Francisco, said to have been convicted of murder in the second degree by the performance of a criminal operation on a young stenographer, was sentenced to twenty years' imprisonment in the San Quentin Penitentiary, November 19.——Julian MacRae, Los Angeles, is said to have pleaded guilty in the United States District Court, November 12, of the charge of unlawfully using the United States mail, and to have been fined $100.——Jose Benito, Oakland, charged with selling medicine not put up by a licensed pharmacist and manufacturing in violation of the state law, is said to have been found guilty in a justice court, November 17. The defendant claimed that the medicine which he was selling cured consumption, asthma, appendicitis, and every other ailment.

ILLINOIS

Assessed for Hospital Expense.—The board of managers of the Whiteside Public Hospital, Sterling, at its meeting November 1, is said to have assessed the eight practitioners who form the corporation, $50 each, to apply on the expenses of the institution.

Personal.—Dr. Charles M. Noble, Bloomington, who was painfully injured in a machinery accident in Sunflower, Miss., has been brought to St. Joseph's Hospital, Bloomington, and is reported improving.——Dr. Frank L. Clemens has been appointed a member of the medical staff of Graham Hospital, Canton, vice Dr. D. Dennison Kirby, resigned.——Dr. Titus P. Yerkes, Upper Alton, has gone to Rochester, Minn., for a surgical operation.

Small-Pox in the State.—Four cases of small-pox are reported in Anna. The schools have been closed and church services and other public gatherings have been interdicted for a few days.——A case of small-pox was found at a cheap lodging house in Chicago, November 14. The 800 lodgers were vaccinated, the hotel was ordered under quarantine, and the patient was removed to the isolation hospital.——Two cases of small-pox were reported in Peoria, November 17, the first to occur in that city for several months.

Chicago

Poses as Physician.—Louis Jappe was fined $100 in Judge Scovel's court, November 17, for practicing medicine without a license. The defendant is said to have claimed to be able to cure epilepsy in three treatments.

Physicians Aid Strikers.—At a special meeting of the West Side Physicians' Club, Dr. Benjamin H. Breakstone suggested that all members of the club furnish medical aid without cost to any striking garment worker applying for assistance. Sixteen members of the club volunteered their services.

Hospital Closes.—After a continuous existence of more than twenty years the Chicago Charity Hospital, 2407 Dearborn Street, has been forced to close its doors because of lack of support. The twenty-seven patients were removed to their homes or other hospitals November 18. Wesley Hospital has purchased the building and grounds.

Personal.—Dr. William E. Morgan, who was operated on for appendicitis at Mercy Hospital, November 25, is reported to be going on well toward recovery.——Dr. and Mrs. Isaac K. Abt have returned from abroad where Dr. Abt has been making a study of hospital construction, with especial reference to hospitals for children.——Dr. Alice Conklin suffered $3,000 loss in a fire which almost destroyed the apartment building in which she resided, November 18.

Health League Formed.—The Citizens' Health Alliance was organized at Hull House, November 27. The main purpose of the alliance is said to be the improvement of markets, improvement of hygienic conditions in schools, the eradication of insanitary conditions in tenements, the improvement of home conditions of school children, the creation of a public sanitary conscience, and the passage of a new ordinance and laws governing the sanitary conditions. The following officers were elected: president, Dr. Hyman Cohen; vice-president, Miss Jane Addams, Alderman A. W. Fulton, and Rev. Jenkins Lloyd Jones; secretary, Mr. G. A. Graves, and treasurer, Miss L. C. Rose.

---

[1] In the form letter which the "National Antituberculosis Association, Chicago." is sending out, signed by John P. Klein, secretary, it is stated: "This association does not ask any club to do this work entirely for charity, as we feel that some compensation should be given for the time and energy used in selling these stamps, and we allow clubs, or individual members of clubs, a commission of 40 per cent., so that on every $10 worth of stamps sold the club or person selling the stamps makes a revenue of $4."

Hospital Notes.—The Union Park Hospital has been incorporated with capital stock of $100,000. The building will be erected on Washington Boulevard west of Union Park, will accommodate seventy-five patients, will be ready for occupancy in a year, and will be under the charge of Dr. Charles C. O'Byrne.——An $80,000 addition to the Norwegian Deaconess' Home and Hospital was formally dedicated November 20. The building is 120 feet long, 50 feet wide, and 4 stories and basement in height, and is to be used as a hospital and deaconess' home. With the old building, the institution now has accommodation for 100 patients and fifty deaconesses. ——Health Commissioner Evans has asked the finance committee of the city council to set aside $1,500 for furnishing the Iroquois Memorial Hospital, the cornerstone of which was laid several weeks ago, and which is now fast nearing completion.——A meeting was held at the Bethel African Methodist Episcopal Church, November 13, to further plans for the establishment of a home for the prevention, cure and treatment of tuberculosis, to be called the Paul Laurence Dunbar Sanatorium. The board of directors consists of Dr. Anna R. Cooper, president; Mrs. L. Waller, secretary; Mrs. F. Turner, treasurer, and Rev. D. P. Roberts.——Plans are under way for the establishment of a day-and-night clinic for tuberculosis patients in connection with the dispensary system of the Municipal Tuberculosis Sanatorium. It is expected that the new sanatorium will be located in the Iroquois Memorial Hospital.

INDIANA

Public Gatherings Interdicted.—As there have been more than 50 cases of diphtheria in Linton during the last two weeks, the city board of health has issued orders that all churches, public schools, moving-picture shows, skating rinks, theaters, pool rooms and billiard halls, and other places where crowds gather be closed.

Appoints Board.—The governor has appointed the following board of trustees for the State Tuberculosis Hospital recently built near Rockville: Dr. Henry Moore, Indianapolis, Dr. Oliver V. Schuman, Columbia City, and Mr. Isaac Strouse, Rockville. The hospital is ready for occupancy but no funds are available for its maintenance.

Personal.—At a recent election in Indianapolis, Dr. Charles O. Durham was elected coroner and appointed the following deputies: Drs. Ralph S. Chappell and M. Cortez Leeth.——Dr. Charles W. Stolzel, for several years in practice at Springhill, Tenn., has returned to Indianapolis.——Dr. Louis A. Bolling, Attica, has become medical director of Mudlavia, Kramer, Ind.

First-Aid Outfit in Patrol Boxes.—Dr. Jewett V. Reed, superintendent of the Indianapolis City Dispensary, has suggested that each patrol box in the city be equipped with a tourniquet and a first-aid package. Many people who suffer from accidents on the streets, have had to wait for the arrival of the ambulance, and by this method the police might apply first-aid dressings at once.

Advertise Tuberculosis Clinics.—A new method for the advertising of the benefits of free tuberculosis clinics will be inaugurated in Indianapolis, December 15. A meeting will be held in Tomilson Hall at which Ex-Mayor Charles A. Bookwalter will preside and which will be addressed by Dr. Charles O. Probst, Columbus, Secretary of the Ohio State Board of Health. Invitations will be issued only to employers and their employees, the object being to show the employers that from a purely business standpoint, cooperation with a clinic will more than repay them.

Recommendations to Legislature.—At a special meeting of the State Board of Health, November 26, the following recommendations to the next legislature were decided on: medical inspection of school children; regulation of building of schoolhouses and providing that every schoolhouse built hereafter must be approved by the State Board of Health and must be sanitary in every particular; additional legislation governing the pollution of streams; additional legislation protecting the water supplies in the state; additional legislation governing the construction of sewers, and lodging in the State Board of Health the supervision of sewer construction so as to guarantee scientific sewerage systems; the enactment of legislation tending to reduce blindness by compelling physicians and midwives to give proper attention to the eyes of children immediately after birth; legislation to control hydrophobia by placing an additional tax on dogs, with which to raise and maintain a Pasteur institute for the free treatment of victims of rabid dogs; giving the inspectors of the state pure food and drug department authority to inspect weights and measures and to file affidavits for maintaining false weights and measures and making it incumbent on prosecuting attorneys to prosecute; amending the pure food law so as to make it possible by insertion of the word "himself" to prosecute the owners of dairies and creameries who are found to be adulterating milk and milk products, and amending the pure food law so as to prevent the traffic in decayed eggs by the insertion of the word "knowingly."

Pure Drugs.—The Indiana Physicians' Pure Drug Association, was formed in Indianapolis, November 20, and the following officers were elected: Dr. Edmund D. Clark, president; Dr. Charles E. Cottingham, secretary-treasurer, and Dr. Frank M. Morrison, Dr. Frederic C. Heath, Dr. Thomas C. Kennedy and Dr. G. H. Roberts, vice-presidents, all of Indianapolis. The objects of this organization are to enforce the state and national pure drug laws as well as to secure better. The reports from the state laboratory show that during the year ended last September, 444 samples of drugs were analyzed. Of these 242 were legal and 202 below the standard. Out of ninety-two samples of spirits of camphor twenty-eight were found to be legal, and 64 illegal. Out of seventy-two samples of tincture of iodin only twenty-six were found to be legal, while forty-six were illegal. In tincture of iron seventeen were legal, and sixteen illegal. In fluid extract of belladonna six samples were legal and seven illegal. When the physicians of Attica received this report they agreed to refuse to buy supplies, even full strength drugs, from those houses shown by these bulletins to be guilty of making any weak drugs. This attitude is characteristic of medical men throughout the state. They refuse to take any chances, and say it is impossible to protect their patients unless the drugs used are pure and full strength. Four of the pharmaceutical manufacturers in the state have been prosecuted for violations of the pure drug laws, but the fines and court costs have not been over $22 in any case. This absurd sum is only a small part of the profit that can be made on the sale of a single barrel of below-standard drugs.

KENTUCKY

New Rule for City Hospital.—At a meeting of the staff physicians of Louisville City Hospital, which was held November 17, over which Dr. Joseph B. Marvin presided and at which Dr. Henry Enos Tuley acted as secretary, a set of rules was adopted governing the physicians and interns of the hospital.

County Society Meeting.—The Hardin County Medical Society held its annual meeting in Elizabethtown, November 10, and elected the following officers: president, Dr. D. Elmo McClure, Sonora; vice-president, Dr. John R. Cowherd, Vine Grove; secretary, Dr. John M. English, Elizabethtown, and delegate to the state medical association, Dr. James C. Mobley, Elizabethtown.

Sanatorium Needs New Buildings.—For the purpose of erecting the necessary buildings for curable cases of tuberculosis and an infirmary for advanced cases, and to pay off the debt incurred before the opening of the institution, the trustees of the Louisville Antituberculosis Association Sanatorium have begun a campaign to secure subscriptions for the $26,000 needed for these purposes.

Meeting of Eastern Kentucky Physicians.—The Eastern Kentucky Medical Association held its annual meeting in Winchester, November 16, and selected Richmond as the place of next meeting. The following officers were elected: president, Dr. J. H. Schultz, Jeffersontown; vice-president, Dr. John P. Huff, Plummer's Landing; Secretary, Dr. Thomas A. E. Evans, Farmers, and treasurer, Dr. William M. Price, Dabney.

Dinner to Dr. Bodine.—Dr. James Morrison Bodine, president of the medical faculty of the University of Louisville, and for forty-one successive years its dean, has been tendered a testimonial dinner to be given at the Seelbach Hotel, Louisville, December 16, to which his pupils and friends throughout the country are invited. Dr. Isadore N. Bloom, Atherton Building, Louisville, is chairman of the committee which has the dinner in charge.

Louisville

Bakeries Inspected.—All of the bakeries in Louisville have been inspected twice by the Pure Food and Drug Division of the Kentucky Experiment Station and the results of the inspection reported to each bakery. All bakers who were heavily scored were given a personal hearing by Mr. R. M. Allen, chief of the division. Of the 150 bakeries which were inspected, thirteen had not made a substantial attempt to comply with the law as found on the third inspection, and prosecutions resulted. Twelve pleaded guilty and one was tried, found guilty, and sentenced to pay a fine of $50 and to imprisonment for ten days in jail. The individual sentenced is said to have conducted his plant in a very filthy cellar, and to have used such ingredients as imitation jellies and anilin egg color substitute. The rest of the bakers are reported as having made most substantial progress in complying with the regulations of the department.

Pure Drug Prosecutions.—The Kentucky Experiment Station, through the head of the Pure Food and Drug Division, R. M. Allen, has brought a number of prosecutions in magistrates' courts in Louisville and has obtained convictions and fines against druggists for selling products below the standard prescribed by the United States Pharmacopeia. The principal products examined and found deficient are as follows: tincture of iodin, seven cases, varying from 47 per cent. to 84 per cent. of the required strength and from containing no potassium iodid to 43 per cent. of the required strength and one sample with undissolved potassium iodid; acetic acid, 76 per cent. of the required strength; tincture of opium, 12.8 per cent. of the required strength; camphor liniment, seven cases, varying from 14 per cent. to 58 per cent. in strength, one sample containing paraffin oil; lime water, being 27 per cent. of the required strength; and precipitated sulphur, 40 per cent. In Covington and Newport other cases are being reported for prosecution; most of them of similar nature with the exception of a firm prosecuted for selling witch hazel containing wood alcohol and a case of another firm for selling zinc oxid containing 90 per cent. of silica. Glycerin, sweet spirits of nitre, collodion, alcohol, citric acid, and tartaric acid are still under consideration because of questions with respect to deterioration or manufacture. The department is trying to determine in each case of a deteriorated product whether it is due to the fault of the manufacturer, the wholesaler, or the dealer, and the division is making an attempt to educate the Kentucky trade with respect to the proper preservation of perishable drug products.

LOUISIANA

Room for More Tuberculosis Patients.—The Louisiana Antituberculosis League announces that there is room in Camp Hygeia for ten more patients in the first stages of tuberculosis.

Sentenced to Life Imprisonment.—Dr. Emmett C. McKowen, Jackson, convicted of the murder of E. K. Judson, New Orleans, an inmate of the State Insane Hospital, Jackson, is said to have been taken to the penitentiary to begin serving his sentence of life imprisonment.

State Health Train.—The health exhibit train, to which The Journal recently referred, is making a tour of the state. Great interest is manifested in the exhibit and in the lectures delivered at the towns at which it stops. The chief subjects dealt with by the lecturers who accompany the train are "Pure Food," "Tuberculosis and Its Prevention," and "Sanitation." The train is equipped with complete anatomic and pathologic exhibits supplied by the Medical Department of Tulane University, the Souchon Museum of Anatomy and the federal and state governments.

Personal.—Dr. John L. Scales, formerly of Alden Bridge, has returned after eighteen months in London and Vienna, spent in special work on diseases of the eye, ear, nose and throat, and associated himself with Dr. Oscar Dowling, Shreveport.—Dr. Gustav Mann, professor of physiology in Tulane University, who sustained serious injury to the head in an accident due to the breaking of a centrifuge in his laboratory October 31, has recovered.——Dr. William J. Headrick, Logansport, is reported to be critically ill.——Dr. Sidney D. Porter, Moreauville, has been placed in charge of the Hookworm Commission of Louisiana.

MARYLAND

Typhoid Fever.—No new cases of typhoid fever have developed among the cadets at the Naval Academy for several days, and it is believed the epidemic is at an end; 23 cases were reported.——During the week ended November 26, sixty cases of typhoid fever were reported in Baltimore with 13 deaths. Of these forty were in the eastern portion of the city and seven are reported in one family.

Society Meeting.—At the annual meeting of the Queen Anne County Medical Society, at Centreville, November 18, the following officers were elected: president, Dr. James W. Stack, Wye Mills; vice-president, Dr. Rowland H. Ford, Queenstown, secretary-treasurer, Dr. H. F. McPherson, Centreville; delegate to the Medical and Chirurgical Faculty of Maryland, Dr. Norman S. Dudley, Church Hill; and alternate, Dr. William G. Coppage, Church Hill.

Personal.—Dr. John E. O'Neill has been appointed assistant superintendent of the State Tuberculosis Sanatorium, vice Dr. E. W. Glidden, resigned to become superintendent of the Georgia Sanatorium. Dr. Glidden was presented with a gold watch by the patients before leaving.——Dr. Robert T. Winterode, pathologist of the State Hospital for the Insane, Catonsville, has resigned to accept the position of superintendent of the State Hospital for Colored Insane.

MISSOURI

St. Louis

In Memory of Dr. Baumgarten.—The Alumni Association of the Medical Department of Washington University has appointed a committee to raise funds for the erection of a memorial tablet of the late Dr. Gustav Baumgarten, to be placed in the Medical Library Building beside those in memory of Dr. Gregory and Boisliniere.

New Contagious Disease Hospital.—The hospital board, on November 16, appointed a committee to investigate and report plans for the new contagious disease hospital to be located on ground owned by the city between the Municipal Sanatorium and the City Infirmary. Authority has been given to equip the Female Hospital buildings as a temporary contagious disease hospital.

New Hospital.—The Sisters of St. Joseph's Convent of Mercy applied on November 21, for a building permit to erect a hospital and convent to cost $350,000 to be known as St. John's Hospital, on a plat of ground recently acquired, bounded by Audubon Ave., Kingshighway, Parkview and Euclid Avenues. The proposed hospital will be a U-shaped, five-story building which will accommodate 250 patients.

Changes in Hospital Staff.—Dr. Meyer Wiener has been added to the staff of the ophthalmologic department of the City Hospital, and Dr. Alexander E. Horwitz to the department of deformities.——Drs. Martin F. Engman and William H. Mook have resigned from the department of deformities and syphilology.——The medical staff, at its meeting for organization, elected Dr. George C. Crandall, president, and Dr. Hanau W. Loeb, secretary, and directed the formation of an executive committee composed of the chairman of each of the twelve departments of the staff.

NEW JERSEY

Gifts to Preventorium.—The Tuberculosis Preventorium for Children, which was removed from Lakewood, N. J., to Farmingdale last April, has received from the estate of Arthur Brisbane 64 acres of land and a free lease for twenty-five years of the Windsor stock farm comprising 240 acres under cultivation. Nathan Straus has contributed $50,000 toward buildings to be constructed on the farm, and the board of health auxiliary connected with the Association of Tuberculosis Clinics has subscribed $4,500 to build an open shack for which it will select the children. The preventorium will require $50,000 more for buildings and additional memberships of $85,000.

NEW YORK

Prizes for Selling Tuberculosis Seals.—The Committee on the Prevention of Tuberculosis of the State Charities Aid Association offers prizes valued at $5,250 to be divided among cities and villages selling the largest number of Red Cross Christmas Seals per capita of school registration before January next.

New County Sanatorium.—Application was made to the Department of Health, November 3, by the Metropolitan Insurance Company for a hearing on its application to build a sanatorium to cost $100,000 for employees afflicted with tuberculosis. The company desires to build the hospital on Mount McGregor at Moreau, Saratoga County.

Appropriation for Health.—The state has appropriated to guard against sickness in the interior of the state, $180,680; for the suppression of epidemics, $7,500; for tuberculosis exhibits, $10,000; for ophthalmia neonatorum, $5,000; for the cancer laboratory, $39,000; for investigations, $10,000; for the antitoxin laboratory, $1,800; for the hygienic laboratory, $14,000. An appropriation of $242,550 has also been made for the health officer of the port of New York.

Ban on Common Drinking Cup.—The State Department of Health is seeking the cooperation of various railroads operating in this state in abolishing the common drinking cup from trains and railroad stations. They have issued a statement pointing out the dangers of this practice and showing that there is no use for its continuance when a cup can be procured from a "penny in the slot machine." They also show that the same dangers accompany the common towel; in fact, that the common towel may be even more dangerous than the common drinking cup.

Practical Instruction of Health Officers.—The State Department of Health announces a new practical course of instruction open to sanitary officers, local health officers, at Albany, beginning December 7, and continuing for three days. The general subject of instruction at this conference will be water and sewage purification. There will be laboratory talks and demonstrations at the State Hygienic Laboratory, Albany, supplemented by inspections of the water filtration plants at Rensselaer and Albany and the sewage disposal systems at Ballston and Saratoga.

New York City

Samuel Alexander Dead.—As we go to press a notice is received of the death, on November 29, of Dr. Samuel Alexander of New York City, professor of clinical surgery in the Medical Department of Cornell University, aged 51.

Harvey Lecture.—The fourth lecture of the present course of Harvey Society Lectures will be given at the New York Academy of Medicine December 10 at 8:15 p. m. by Dr. Harvey Cushing of Johns Hopkins University on "Certain Clinical Aspects of Dyspituitarism."

Crusade on Smoking Autos.—The sanitary inspectors of the health department have the duty of watching for smoking automobiles, and since November 1 100 arrests have been made, and of this number about seventy have been convicted. The fines for the first eleven days of this month amounted to $127.

New Day-and-Night Tuberculosis Camp.—A new tuberculosis day-and-night camp was opened November 15, in the annex of the New York Throat, Nose and Lung Hospital, 233 East Fifty-Seventh Street. The night camp will be for incipient and moderately advanced cases, and the day camp for patients in all stages of the disease.

Two Deaths from Cholera.—The Italian liner, *San Giorgio*, which arrived from Naples and Palermo with 629 steerage passengers, was held at quarantine for five days. A woman and a child died during the voyage of cholera, the woman being buried a few miles off Sandy Hook. Another child supposed to have cholera was taken to Swinburne Island and bacteriologic examinations confirmed the suspicion.

Hospital to Move.—The New York Society for the Ruptured and Crippled has obtained permission to sell its property at Forty-Second Street and Lexington Avenue to the New York State Realty and Terminal Company for $1,350,000. The New York Central Railroad will get a portion of the property. It is the intention of the trustees to establish a new hospital in New York City and a branch hospital in the country.

Many Diseases on Liner.—The Cunard steamer *Carpathia* arrived November 18 from the Mediterranean with a variety of diseases on board. While there was no cholera, scarlet fever wrought harm to the children of the steerage, five having died and been buried at sea. An epidemic of measles also broke out, and there were thirty-four cases when the vessel arrived at quarantine. There were also two cases of erysipelas and one of typhoid fever.

Advisory Board of Statisticians.—The health commissioner has secured the assistance of Drs. Roger S. Tracy, William H. Guilfoy and Cressy L. Wilbur, Washington, D. C., as members of an advisory board of statisticians to the health department. Associated with these physicians are Prof. C. E. A. Winslow of the City College, and Prof. Walter L. Wilcox of Cornell University, the latter of whom is also consulting statistician to the State Board of Health.

For the Prevention of Insanity.—A special committee on mental hygiene has been appointed by the State Charities Aid Association, which will initiate a campaign for the prevention of insanity. The campaign will be conducted on lines similar to the crusade against tuberculosis. Among the members of the committee are Drs. M. Allen Starr, Charles L. Dana, Frederick Peterson, Bernard Sachs, Albert Warren Ferris, William Mabon and William L. Russell. Mr. Homer Folks is chairman of the committee.

Randall's Island Designs Approved.—Designs for the proposed plan of buildings on Randall's Island, at an estimated cost of $4,500,000, have received the preliminary approval of the Municipal Art Commission. Fifteen groups of cottages for the patients will be situated on the southern, southeastern and southwestern slopes of the island, surrounding on three sides the central school house and the general medical and surgical hospital. The isolation hospital for contagious diseases will be situated on the western shore.

New Clinic.—At a recent meeting of the faculty of the University and Bellevue Hospital Medical College it was stated that funds sufficient for equipment and the maintenance for one year of a clinic for minor surgical operations had been secured. The clinic will handle minor operations which cannot secure free treatment in the city hospitals and which few physicians' offices are equipped to handle. The department will offer students better opportunities for practical observation of methods of modern antiseptic surgery than is possible at more serious operations.

Plans of the Milk Committee.—The New York Milk Committee has obtained a certificate of incorporation which sets forth that the organization proposes to improve the milk supply of New York City and educate the public in the proper use of milk for infant feeding and other purposes. The committee will hold a conference December 2 and 3 for the purpose of discussing the most efficient ways of controlling the municipal milk supply. Physicians, sanitarians, research workers and representatives of the municipal, state and national health and agricultural departments have signified their intention of being present at this conference, and the public has been invited to attend.

Sanitary Code Violated.—Inspectors have reported that the sanitary code has been flagrantly violated all over the city, and Raymond B. Fosdick, commissioner of accounts, has undertaken an investigation. It has been found that breadstuffs are being baked under conditions of "unspeakable filth," and that sulphurous acid has been used in the manufacture of candy and to stay the decomposition of meat. Disgraceful conditions have been revealed in the chicken slaughter houses of the east side, and it is stated that these violations could not have occurred except through the inefficiency or venality of certain of the inspectors. Commissioner Fosdick has heard that large sums of money have been paid to politicians in order that certain interests might obtain permits from the Bureau of Food Inspection to the exclusion of other interests. The Bureau of Chemistry of the Department of Agriculture has, through Dr. Harvey W. Wiley, tendered the use of all the facilities of that office in the investigation to be carried on.

NORTH CAROLINA

Medical Legislators.—At the November election the following physicians were elected to office: congress, Dr. John M. Faison, Faison, Duplin County; state senate, Dr. Robert N. Cartwright, Fairfield; house of representatives, Drs. Alfred A. Kent, Lenoir; John H. Mease, Canton; Robert P. Floyd, Louisburg, and Mark B. Pitt, Tarboro.

Personal.—Dr. Julian E. Wood, Elizabeth City, is said to be critically ill with heart disease at his home.——The office of Dr. R. Vance Brawley, Salisbury, was entered by thieves recently and a number of valuable instruments and fixtures were stolen.——Dr. Henry T. Bahnson, Winston-Salem, has been elected honorary fellow of the Virginia State Medical Society.

OREGON

Personal.—Dr. Walter E. Carll, Oregon City, is a patient in St. Vincent's Hospital, Portland, suffering from a diphtheria infection of the eye.

New Professor of Physiology.—The University of Oregon, Department of Medicine, has secured the services of Dr. John Dice MacLaren of the University of Oklahoma, who will occupy the chair of physiology. It is stated that Dr. MacLaren will devote his entire time to teaching and research.

Sanatorium Opened.—After great delay the State Sanatorium for Tuberculosis opened to receive patients, November 21. There were thirty-seven applications received before the opening of the institution. Thus far $30,000 has been spent in the erection of buildings and maintenance. The institution is located in the old State Mute School building near Salem.

PENNSYLVANIA

Hospital for Doylestown.—A gift of a large sum of money to establish a hospital in Doylestown was announced at a meeting of the Doylestown section of the County Medical Society on November 18. The source of the gift has not been made known and there are conditions requiring the citizens of the town to contribute an equal sum.

Personal.—Dr. William C. White, Pittsburg, has resigned the superintendency of Waverly and Hazelwood Antituberculosis Sanatoriums, Louisville.——The Westchester School Board has elected Dr. Jane R. Baker, Embreeville, examining physician of the school children.——Dr. Charles H. Brown has resigned as health officer of Franklin.——Dr. George Boehm, Arona, was thrown over an embankment 200 feet high in a runaway accident, recently, but fortunately was not seriously injured.——Dr. Morris P. Boyle, Glenside, is reported to be critically ill at Germantown Hospital, Philadelphia.

Philadelphia

Diphtheria Closes a School.—Owing to the illness of several pupils with diphtheria, the John Barry Public School was closed for fumigation on November 18.

To Enlarge Hospital.—Howard Hospital, at Broad and Catharine Streets, has purchased adjacent property on Catharine and Webster Streets for $9,866.66.

Free Clinic Opened.—The Jewish Consumptive Institute, Philadelphia, has opened a free clinic at 406 Wharton Street. The clinic is open every day after 12 o'clock.

Temporary Biologic Laboratory.—The Department of Health of Pennsylvania has leased the building at 2000 Arch Street for temporary use as a biologic laboratory.

Hospital Buys Two Lots.—The German Hospital has purchased the property at the southeast corner of Corinthian Avenue and Cambridge Street and the adjoining property on Corinthian Avenue, lot 40.9x84.9, for $8,000. Both lots are directly opposite the hospital.

Measles on Steamship.—Among the steerage passengers of the American liner *Merion*, which docked November 14, two women and eight children were found to be suffering with measles and were taken at once to the Philadelphia Hospital. The rest of the steerage passengers were discharged.

Epidemics Closed City Schools.—On account of scarlet fever and diphtheria, seven of the city's public schools were closed for fumigation, November 21, by order of the Board of Health. In all except one of these institutions at least two or three cases of contagious disease, scarlet fever or diphtheria were discovered.

Dr. Willard's Will.—Among the bequests included in the will of the late Dr. DeForrest Willard are the following. To the trustees of the University of Pennsylvania is left $300 for a free bed in the Children's Orthopedic Department. To the Union Benevolent Association is bequeathed $1,000 in trust, the income to be applied to the Gladys Willard baby fund. The Christian Association of the University of Pennsylvania receives $250 for settlement work, and the Presbyterian Hospital $1,000.

Officers Elected.—At the annual meeting of the Aid Association of the Philadelphia County Medical Society, the following officers were elected: president, Dr. Roland G. Curtin; vice-president, Dr. Jacob R. Shellenberger; secretary, Dr. Lewis H. Adler, Jr.; treasurer, Dr. John B. Turner; directors (for three years), Drs. Oscar H. Allis, John C. DaCosta and Richard A. Cleeman. In addition to these new directors were chosen to fill the places of the late Drs. DeForest Willard and James B. Walker. These were Drs. Samuel D. Risley and William S. Wray.

Ovation for Dr. Smith.—Edgar Fahs Smith, M.D., vice provost of the University of Pennsylvania and professor of chemistry in the same institution, was elected provost to succeed Charles C. Harrison, at a special meeting of the Board of Trustees, November 15. When this fact became known to the students, every one, no matter what his department, left his classroom and for the first time in years all the students assembled in one vast throng. They made their way to the Harrison Chemical Laboratory to show to Dr. Smith their great rejoicing over his election. Many had been named to fill Dr. Harrison's place, but Dr. Smith was the choice of faculty, alumni and students.

New Hospital Recommended.—At a conference of the State Board of Charities with state officials and the heads of the state insane hospitals in the central district, it was decided to recommend state provision for an institution for the care of the tuberculous insane. The superintendent strongly urged that some provision for such persons be made, owing to the necessity of isolating tuberculous patients. The State Commissioner of Health supported the plan and, on his recommendation, the board decided to include provision for a building and grounds similar to the state tuberculosis sanatoriums. The cost will be from $100,000 to $150,000 and state property adjacent to one of the state hospitals will be chosen.

Personal.—Dr. Charles K. Mills, professor of neurology, and Dr. William G. Spiller, professor of neuropathology at the University of Pennsylvania, have been notified of their election as corresponding members of the Gesellschaft der Deutschen Nervenartzen.——Dr. Charles W. Burr has been elected physician to the Orthopedic Hospital and Infirmary for Nervous Diseases, vice Dr. Wharton Sinkler, deceased. The three chiefs of clinics now are Drs. Morris J. Lewis, John K. Mitchell and Charles W. Burr, with Dr. S. Weir Mitchell as chief emeritus.——Dr. Maurice Ostheimer has been elected physician to the medical dispensary of the Children's Hospital, vice Dr. J. Claxton Gittings, resigned, to accept the position of physician to the Children's Hospital.

WISCONSIN

New Dispensary.—The Milwaukee Maternity Hospital and Free Dispensary Association opened its south side free dispensary for the sick poor, 391 Mitchell Street, November 16. A benefit for the dispensary was given at the Majestic Theater, November 22.

Found Guilty.—Fletcher P. Riley, charged with using obscene medical advertising in newspapers, is said to have been found guilty October 28, on five separate charges and fined $25 and costs in each case. His assistant, Benjamin W. Kinsey, is said to have pleaded guilty and to have been fined $50 on each count.

Bubbling Fountains.—The Health Commissioner of Milwaukee has asked that two bubbling fountains be placed at each entrance or inside the lobby of the Auditorium Building for the accommodation of patrons.——Two bubbling fountains were installed on West Water Street in Grand Avenue by the health department recently.

Public Health League Organized.—At a meeting of the people of Kenosha, October 25, plans were completed for the incorporation of the Kenosha Antituberculosis and Public Health League, a reorganization of the Kenosha Antituberculosis Committee. The new organization will be in close affiliation with the state and national organizations.

Personal.—Drs. George J. Jurss, Arthur R. F. Grob and Gustave A. Hipke have been appointed trustees of the Emergency Hospital, Milwaukee.——Dr. George R. McManus, health officer of Stoughton, is reported to be seriously ill with septicemia.——Dr. Frank E. Darling has been appointed assistant health commissioner of Milwaukee, vice Dr. Louis F. Jermain, who, on his return from Europe recently, resigned.——Dr. Richard J. Fleischer, Milwaukee, was seriously injured in a street car collision recently.——Dr. Christian Bergh and family, Whitehall, have returned from Norway.——Dr. Edward W. Quick, Appleton, has removed to Greenbay, where he will be chief of staff of St. Vincent's Hospital.

GENERAL NEWS

New Publishers for Journal.—The Rebman Company, New York City, announces that at the beginning of the year, it will take over the publication of the *Journal of Cutaneous Diseases*.

Meeting of Hawaiian Society.—The annual meeting of the Hawaiian Territory Medical Society was held in Honolulu, October 29-31, and the following officers were elected: president, Dr. W. G. Rogers; vice president, Dr. W. D. Baldwin; secretary-treasurer, Dr. William C. Hobdy, and executive committee, Drs. St. David G. Waters and Clifford B. Wood, all of Honolulu.

Museum of Safety.—The American Museum of Safety, whose object is the conservation of human life, was formally opened at the United Engineering Society Building, 29 West Thirty-Ninth Street, New York City, November 21. The organization proposes to erect a museum of safety and sanitation which will be a clearing house for every worthy device and every worthy thought for safety.

Soo Line Surgeons Hold Meeting.—The fourth annual meeting of the Minneapolis, St. Paul and Sault Ste. Marie Surgical Association was held in St. Paul, November 16 and 17, under the presidency of Dr. Justus Ohage, St. Paul. The following officers were elected: president, Dr. Albert E. Halstead, Chicago; vice-president, Dr. Charles F. McComb, Duluth, Minn.; and secretary-treasurer, Dr. John H. Rishmiller, Minneapolis, Minn. The next meeting will be held in Chicago.

Personal.—Dr. Kenneth W. Millican, formerly a member of the editorial staff of The Journal, sailed, November 4, for England on invitation of the *Lancet* to take a position on its editorial staff.——Dr. Samuel T. Darling of the Ancon (C. Z.) Hospital Laboratory and J. J. McGuigan of the Panama Health Office, left, October 24, to investigate the report as to small-pox in the Province of Los Santos.——Dr. H. J. Howard, formerly of Rochester, N. Y., has been appointed chief of the ophthalmological staff of the University of Pennsylvania Medical School and Hospital, Canton, China, and will sail for his new post of duty December 13.

Tri-State Physicians Meet.—The Tri-State Medical Society of Arkansas, Texas and Louisiana held its annual meeting in Shreveport, La., November 15 and 16, under the presidency of Dr. Robert H. T. Mann, Texarkana. The following officers were elected: president, Dr. Thomas P. Lloyd, Shreveport, La.; vice-presidents, Drs. Edward H. Martin, Hot Springs, for Arkansas; Thomas J. Allison, Gladewater, for Texas, and Robert H. Blackman, Monroe, for Louisiana; councilors, Drs. Robert F. Kittrell, Texarkana, for Arkansas; Clarence M. Tucker, Haughton, for Louisiana, and Samuel F. Vaughan, Jonesville, for Texas, and secretary-treasurer, Dr. Jacob M. Bodenheimer, Shreveport, La. (reelected).

Nu Sigma Nu Convention.—The sixteenth biennial convention of the Grand Chapter of the Nu Sigma Nu Medical Fraternity was held in Cleveland November 25 and 26. Applications for charters were received from students in the medical departments of Wisconsin University and of Tufts College; both were refused. The following officers were elected for the ensuing two years: Dr. Torald Sollmann, Western Reserve, to succeed Dr William H. Welch as honorary president; Dr. Frank F. Wesbrook, University of Minnesota, as honorary vice-president; Dr. R. Burton Opitz, Columbia University, honorary secretary; Dr. Harold A. Miller, Pittsburg, honorary treasurer, and Dr. William H. Parks, New York, honorary historian. The acting executive officers elected were Dr. Henry J. Prentiss, Iowa University, president; Dr. Ernest E Irons, Rush Medical College, secretary and treasurer, and Dr. Henry W. Stiles, Syracuse University, grand custodian.

FOREIGN NEWS

Personal.—Dr. A. Pulido, member of the Spanish parliament and one of the editors of the *Siglo Medico*, recently received the decoration of the grand cross of the order del Merito Militar and at the same time was presented with an album containing the autographs of all the army professors as a token of gratitude for his efforts in and outside of the legislature to improve the medical service in the army and enhance its prestige.

Ehrlich's "606" and the Italian Dermatologists.—At the annual meeting of the Associazione dei Dermatologi Italiani resolutions were adopted in regard to Ehrlich's new remedy for syphilis, calling attention to the harm that may result from the way in which it has been advertised and warning the public against interested exaggeration of its therapeutic efficacy. Physicians are urged not to charge exorbitantly for injections of the new drug when it is put on the market, as some are said to have done already.

The Pirogoff Centennial.—The profession in Russia celebrated in various ways, November 26, the hundredth anniversary of the birth of Nicolai Pirogoff, the great Russian surgeon, chief of the military medical service during the Crimean and the Russo-Turkish wars, and long professor of surgery at the Military Academy. His first work, published in 1836, on the anatomy of arteries and fascia not only gave him an international reputation but blazed the way for the surgery of the future. The national medical association of Russia has for its official title, the "Society in Honor of the Memory of Pirogoff."

Deaths in the Profession Abroad.—In addition to the deaths mentioned by our foreign correspondents, the profession has lost Dr. R. U. Krönlein, until the last few months professor of surgery at Zurich, Switzerland, and a frequent contributor to surgical literature, aged 63. The twenty-fifth anniversary of his connection with the Zurich faculty was celebrated by his friends in 1906.——From Buenos Aires is reported the death of two members of the medical faculty of the university, Drs. O. Hernandez and R. H. Vegas, professors of pathology and surgery, respectively.——Dr. A. Hauser, of Teplitz, the leading spirit in the successful organization of the profession in Bohemia in recent years and in numerous lines of preventive medicine and in determining the therapeutic radioactivity of the mineral springs of Bohemia, died suddenly at Teplitz, recently, aged 39. He was one of the first to emphasize the necessity for a press committee as a powerful means to further the interests of the organized profession.——S. Mayer, professor of histology at the German University of Prague.——Dr. E. Below of Hannover, well known as a literary writer, especially on America, where he had long resided, died October 31, aged 65.——Dr. Lombe Atthill, University of Dublin, formerly president of the Royal College of Physicians, Ireland, vice-president of the Dublin Obstetric Society from 1900 to 1903, president of the Royal Academy of Medicine in Ireland, whose work entitled "Lectures on Diseases Peculiar to Women," is well known and ran through many editions, died at Stroud, Kent, September 14, from heart disease, aged 82.——Dr. John Anderson, F.R.C.P., for many years an officer in the Royal Army, Medical Corps, and later a specialist in tropical medicine and a general consulting physician, died at his home in London, October 10, from cerebral hemorrhage, aged 70.——Dr. Sidney Ringer, consulting physician to University College Hospital and Holme professor of clinical medicine in University College, London; the author of "Handbook of Therapeutics"; a clinician and pharmacologist of great repute, died at his country residence in Yorkshire, October 14, aged 75.

MANILA LETTER

(From Our Regular Correspondent)

Manila, Oct. 21, 1910.

New Water-System for Manila

The new water-system for Manila has been inaugurated and accepted by the municipal board. This insures not only more but also vastly better water for Manila's inhabitants. The main reservoir back of the dam, which has a capacity of 500,000,000 gallons, is fed by the waters of the Mariquina River which rises high in the mountains of Central Luzon. For several years the water-supply of Manila has been inadequate and not altogether free from pollution. The protection of the city's new water-supply is guaranteed by the Mariquina reservation water-shed near Bosoboso, where a great area, more than 100 square miles in extent, is a safeguard against pollution of the water flowing into the Montalbon reservoir. This area is absolutely uninhabited; it is owned by the city and no one will be allowed to settle there. No filtration plant is included in the present system, nor is any planned for the immediate future, partly because of lack of funds, and partly because up to the present sanitary engineers have not devised a filtration plant which will deliver water free of amebas to the mains. The amebas, although much larger than many micro-organisms which are taken out by filtration plants, seem to pass readily through each of the various types of filters. As the contamination of the present water-supply is mostly that of amebas, the city is content to let the filtration plant rest till further successful experiments have been made along this line.

Almost No Cholera in Manila

The cholera situation in Manila at present has only one lamentable aspect. The physician from the Bureau of Science who has been carrying on investigations on cholera at the San Lazaro Hospital for infectious diseases is rather disappointed that the number of cases for the past few weeks has not been sufficient even for purposes of investigation. While southern Europe is suffering and excited over epidemics of cholera, Manila, with whose name cholera has so long been closely associated, goes for one, two, three or more weeks without seeing a case; this, too, right in the midst of the rainy season. The director of the Bureau of Health says that the quarter ending Sept. 30, 1910, has been perhaps the most satisfactory from the standpoint of the occurrence of infectious diseases, of any quarter since American occupation. Similar encouraging reports in regard to cholera also have been received from the provinces.

The Philippine Islands Association for the Study and Prevention of Tuberculosis

Through the influence of the Philippine Islands Association for the Study and Prevention of Tuberculosis school children are taught how tuberculosis spreads, its effects, and the personal sanitary precautions necessary to avoid the disease in the Philippine Islands Popular lectures on tuberculosis have been given at the churches and at some of the clubs The police stations, the schoolhouses and other municipal buildings have been used as places for instructing the native how to care for himself These public "clinics" are to be held from time to time in all parts of the city The director of health has declared tubercu' [illegible] ommunicable disease which thus becomes [illegible] to the sanitary code of Manila The pc [illegible] been liberal in subscribing funds and commodities to carry on the work of the society, and these subscriptions have enabled it to open up a simple fresh air sanitarium at the edge of town for treatment and the isolation of advanced cases

New Medical Journal

A new monthly medical journal, the *Revista de Medicina y Farmacia*, has begun publication in Manila This journal is in Spanish and is the official organ of the Colegio Medico-Farmaceutico de Filipinas and to a greater or less degree of that portion of the medical profession in Manila who do not speak English

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Nov 19, 1910

The Falling Birth-Rate

In the quarter ending September the births in England and Wales were in the proportion of 24 9 annually per thousand of the population This is the lowest birth rate recorded in any third quarter since the establishment of civil registration The deaths were in the proportion of 11 4 annually per thousand persons living, which is the lowest death rate recorded

The Institute of Hygiene

The Incorporated Institute of Hygiene is a peculiar and very useful body to which there is probably no parallel in other countries Like many other institutions in this country, where so much is left to private initiative that is done by the government in other countries, it discharges important public functions. The governing body consists of some of the most eminent physicians in the country There is a council of over fifty which devotes itself chiefly to awakening interest and spreading knowledge in regard to hygiene The feeding and rearing of children, the responsibilities of motherhood, the hygiene of the home, food and dietetics, cooking, physical training and home nursing are some of the subjects comprised Many lectures by authorities on these subjects are arranged by the institute Examinations are organized and held periodically in every large center in the United Kingdom and many young women and men enter as candidates to secure the certificate of the institute Many of these candidates are school teachers, who will use their knowledge in teaching Museums, too, have been established as centers of information in regard to foods, beverages, clothing and domestic hygiene Perhaps the most valuable work done by the institute is that of maintaining and raising the standard of purity and quality of food The means are very simple The maker is invited to submit his product for examination, samples are received and are also bought in the open market These are analyzed in the laboratory A report is drawn up and comes before an examining board which sits every month and is composed of members who have attained distinction in analytical work The claims made for the article are considered Those articles which are found to be pure and up to the standard of their claims are granted the certificate of the institute This is issued for only one year and a condition of its renewal is that the purity and standard of the article must be maintained As the results of the analysis are registered at the laboratory a strict watch is kept on the articles certified The greater part of the funds of the institution have been contributed by the members of the council but an appeal is now being made to the public for funds to extend the work to all the large centers of population

The Epizootic of Rat Plague

The systematic destruction of rats in the plague infected districts of Suffolk, described in my last letter [November 26, p 1903] has been carried out with most effective results in the last fortnight Men employed for the purpose of destruction are making house to house visitations to inquire if there are any rats on the premises and to offer to destroy them Persons who are believed to have an unusual number of rats or mice on their premises are receiving notices from the sanitary inspectors requesting them to take measures for the abatement of the nuisance The government has conferred on the local authorities special powers for the destruction of rats in districts where plague is present or suspected or in which there is an unusual mortality among rats A memorandum on plague describing its early symptoms and means of prevention has also been issued As it is now nearly two months since the four cases of plague in man, recorded in previous letters to THE JOURNAL, have occurred and no suspicious cases have followed, the danger of an epidemic of the disease is considered slight The danger of plague attacking Europeans is emphasized in a letter to the *Lancet* by Professor W J Simpson, a well-known authority on tropical diseases, who has been sent by the government to the tropics to inquire into several epidemics of plague and other diseases In the outbreak of plague at Capetown, South Africa, a comparatively small town, he found that the cases were distributed as follows Europeans, 164, colored (Asiatics, etc) 342, and natives 133 Rats died a considerable time before the outbreak, but their connection with human plague was accepted only in a half hearted manner and proper precautions were taken only late in the outbreak

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Nov 11, 1910.

Arsenobenzol (606) at the Society of Dermatology

The Societé de dermatologie devoted its November session almost exclusively to the study of (1) the efficacy of "606," and (2) the technic of the injections Professor Bayet, of Brussels, reported results in 100 cases (he treated 175, but the last seventy five had not been observed long enough to justify a report) Bayet used Wechselmann's procedure with injections in the interscapular region These injections often caused troublesome local consequences, persistent infiltrations, even gangrenes, one of which lasted six months without cicatrizing The general effects were not serious a little fever and kind of arsenical rheumatism, sometimes erythemas Bayet found arsenobenzol efficacious, especially in certain cases, it is perhaps, he thinks, a more active remedy than mercury On the other hand, it fails to act in certain cases of primary and secondary syphilis, offers no guarantee against recurrences, which are frequent, and has scarcely any effect on the Wassermann reaction

Dr Brocq, physician of the St Louis Hospital, reported results which he obtained in the treatment of twenty syphilitics for a month by Ehrlich's method, which he compared with results from the old methods of treatment Brocq thinks that the mercurial treatment has changed somewhat within ten years Gray oil, which on account of the facility with which it can be employed has come into general use, is an unreliable remedy apart from its danger Little by little syphilologists who employ it almost exclusively have become accustomed to obtaining only imperfect results, hence their admiration for the results given by 606" But mercury should be in the form of calomel or injections of the soluble salts, or even of Van Swieten's solution taken internally and associated with iodids, to be fairly compared with "606" One almost never sees a case really intractable to mercury in these forms Some have asserted the superiority of arsenobenzol over mercury because in certain cases an injection of arsenobenzol has had a beneficial effect on conditions which prolonged mercurial treatment would not cure, but in such cases arsenobenzol has had only the effect of arsenic administered in the old forms, such as tonics and sulphurous waters, which after long mercurial treatment often bring about a cure of hitherto refractory conditions One can, therefore, judge of the action of the drug only in entirely untreated cases, in which it appears to be an excellent antisyphilitic remedy which ought to be placed by the side of mercury If it is to become generally used, however, it needs to have the technic of injection perfected Its efficacy is sometimes perhaps superior to that of good mercurial treatment in moist syphilides, in precocious malignant syphilides and in tertiary ulcerations of the mucosæ It is almost equal to that of mercury in certain papulous syphilides and in ulcerating tertiary syphilides of the skin It seems inferior to that of mercury in certain roseolas and in acneiform and tuberculosquamous syphilides No longer periods of immunity from complications seem to be afforded by arsenobenzol than by good methods of mercurial treatment It seems, then, that the new remedy ought not to replace mercury and the iodids in the treatment of syphilis, all the more since the contra-indications to its use are so important that the detractors of the remedy say that arsenobenzol is a remedy for syphilitics who are rather healthy.

Drs. Levy-Bing and Lafay advise the use of oil as the vehicle to diminish the pain which accompanies the injection. Their method is like that recommended by Kromayer in Germany, but a different kind of oil is used. Levy-Bing and Lafay use a mixture of one part of hydrated wool fat to nine parts of poppy oil. These injections of "606" in an oil medium are well borne. There is no pain at the time of the injection, and the patients are not obliged to keep to their beds. Dr. Emery, who has just made an investigation in Germany on results obtained from various present-day methods, admits that injections in oil emulsions seem less painful and irritating than the injections used by Wechselmann, but both have the important disadvantage of sometimes becoming encysted and of being slowly absorbed always. The intravenous injections recommended now by Ehrlich, to be repeated several times followed, after some days or months, by an intramuscular injection, constitute the treatment of choice.

Dr. Milian remarks that although with the oil preparations there is little or no pain at the time of injection, that is really of small consequence, for the immediate pain lasts only a few minutes. What counts is the pain later on, which is produced the third or fourth day. The latter is almost inevitable, for it is due, not to the method employed, but to the absorption of the drug and to the inflammatory reaction provoked in the tissues.

Mortality from Tuberculosis in France

At the Académie de médecine on November 8, Prof. Albert Robin remarked that the statistics which gave France an unfavorable position in the ranks of tuberculosis mortality, attributing to it 150,000 deaths annually, were inexact. According to the official statistics of the ministry of the interior, the number of deaths from tuberculosis in 1908, for example, was only 85,271, or 21.7 deaths per 1,000 inhabitants. Some of the deaths from tuberculosis are recorded under categories such as acute bronchitis, chronic bronchitis, diseases of respiratory organs, etc.; but the number of deaths in these various classes continues to diminish from year to year like the deaths from tuberculosis. The indications are that the campaign against tuberculosis in France is efficacious, although sanitariums are less used here than in other countries.

The Insufficiency of the Equipment of Our Clinics

On his return from Copenhagen, where he had been invited to be present at the inauguration of the new Rigshospital clinics, Prof. J. Teissier, of Lyons, published an article comparing the parsimony of allowances made to our services of instruction and the insufficiency of the equipment of our laboratories with the richness of analogous equipments abroad. Professor Teissier thinks that there is no more need to discuss the respective merits of a corps of *agrégés* appointed after a more or less perfect competition or of a privat-docent system about which some are beginning to complain in Germany and which Italy thinks of replacing by our much-abused *concours d'agrégation*. The first necessity is to provide the necessary equipment and income and to liberate medical instruction from the public charities and from the hospital administrations by creating government establishments for the purpose. Professor Quénu, of Paris, likewise complains of the insufficient funds for clinical instruction; the annual budget of the laboratory attached to Dr. Quénu's surgical service does not exceed $400 (2,000 francs).

Repair of the Damages from the Fire in the Toulouse Medical School

On the day after the fire which destroyed the library of the Toulouse medical school, the ministry of public instruction ordered an investigation of the results of the fire. There were over 150,000 volumes, brochures, theses, etc., destroyed. They were insured for $50,000 (250,000 francs), but they were worth much more. The university is requesting donations of duplicates and original publications from French and foreign universities and institutions of learning—a plan successfully employed by Turin and Ottawa after their libraries were destroyed by fire.

Personal

In its session of November 8, the Académie de médecine elected two foreign associate members, Professors Loeffler, of Greifswald, and Retzius, of Stockholm.

BERLIN LETTER

(*From Our Regular Correspondent*)

BERLIN, Nov. 10, 1910.

The Puro Trial

The court process against the maker of the "Puro" meat juice, which I reported to you last year has had a second trial after an appeal by the convicted manufacturer, Dr. Scholl. After the evidence of various medical experts, both for and against the accused, he was convicted this time not of fraud but of breaking the food law and was condemned to a money fine of $250 (1,000 marks) but not to imprisonment. As a basis of the verdict, it was shown that the statements in the advertisements and on the labels were incorrect, and that the claim of the accused, that these statements had inadvertently been allowed to remain after the change in the manufacture of "Puro," was not credible. No property injury was assumed, as it was considered proved that the material was utilizable for its purpose and that the price was not exorbitant. Dr. Scholl has also appealed from this ruling.

Peculiar Fee Offered to a Physician

In a hunting magazine a few weeks ago, the following amusing advertisement appeared: "Opportunity to hunt a good stag is offered to a well-known authority in diseases of women. As compensation it is required that he make a correct diagnosis of the case of my wife during his stay at the hunting lodge." It is not known whether he has found a gynecologist to undertake the task.

Official Circular Regarding the Use of the Nursing-Bottle

With reference to the question of introducing or rejecting a law like that of France, forbidding the sale of all nursing-bottles with a tube, the question has been asked the Prussian authorities whether regulations on this matter should be established. The minister of education has inquired of his subordinates whether the use of this form of bottle is increasing or diminishing, what its disadvantages are and to what extent industrial interests would be affected by forbidding its use.

Literary Books for Physicians

The members of the Hamburg medical society numbering several hundred, have determined to place in their library a department for literary works which have been written by physicians or in which physicians or medical questions play a large rôle. These books are to be accessible to the members in the same way as the other departments of the library.

VIENNA LETTER

(*From Our Regular Correspondent*)

VIENNA, Nov. 15, 1910.

A Forest and Garden-Zone Around Vienna

Some weeks ago, a new park, constituting another link in the chain of parks and gardens around Vienna, was opened in this city. The idea of ensuring a constant supply of pure air for this city with its sad distinction of being a hotbed of tuberculosis is due to the late mayor of Vienna, with whom the gratitude of the future generations will always associate the "garden-zone." Owing to the enormous growth of the city, the outskirts are being studded with factories and buildings; the prevalent winds, northwest and southeast, have always brought smoke into the heart of the city. The late mayor, in spite of very powerful opposition, caused a law to be passed which prohibited the erection of factories within a radius of 10 kilometers (6 miles) from the center of Vienna; furthermore, an area of some 500 to 1,400 meters (⅓ to 1 mile) has to be kept free from buildings all around Vienna. This space has been converted into a garden ring and when completed, will encircle the capital like a continuous belt of parks, meadows and woods. An abundant supply of water for ponds and ornamental cascades has been provided. The population has been quick in learning the advantages offered them by the splendid air-reservoirs and already this ring is a favorite playground for the children.

A Medical Insurance Company

The repeated occurrences of conflicts between insurance companies and their medical men as well as the high premium demanded by the companies for the insurance of our professional brethren against accidents as well as invalidism, have had an unexpected result. A short time ago, the Medical Organization Committee began to agitate for a medical insurance company, to be run by medical men for medical men, with money coming from the profession. This was achieved very quietly, in spite of great opposition from the existing companies, and now the "Kosmos," as the new society is termed, has taken up its work. Subscriptions came from physicians from all the empire, and the funds at disposal are much larger than originally expected. The premiums of Kosmos are much below those asked by other companies, so that the general public has already availed itself of this opportunity. The fact that medical enterprise was able to make the profession independent in this respect has caused much surprise, and will undoubtedly strengthen its position in other respects, too.

Austrian Cancer Society

After long preparation, the Austrian Cancer Society has held its first meeting recently. Its purpose is twofold: The scientific campaign against malignant growth will be conducted in special cancer-research institutions, and public instruction as to the nature and necessity of the early removal of cancer will be attempted on liberal lines. For the research the leading pathologists and surgeons of the Vienna University (Weichselbaum, Paltauf, Eiselsberg, Schauta) have become members of the committee which will manage the society. The other branch of the work will be carried on by the distribution of popularly worded leaflets dealing with cancer, the institution of lectures for the middle and lower classes both in towns and rural districts and last, not least, the admonition of practitioners to prevent undue loss of time and chance. The late Professor Chrobak caused to be distributed in his gynecologic clinic similar leaflets with a warning as to breast and uterine cancer.

Hungarian District Medical Officers

A law, passed in 1908, requires every community of more than 5,000 inhabitants to provide a district medical officer, who must hold a diploma as doctor of public health. For this purpose the whole country has been divided into sanitary districts. The number of men necessary to fill these posts is 350. But the budget of the Hungarian government provides for only eighty-three such posts. The payment is 1.600 kronen ($320) and no old-age provision. Naturally the standard of sanitation in the rural districts is a very low one in this country. Even the recent outbreak of cholera did not convince the local magistrates of the necessity for unusual measures and proper medical supervision of the country.

Marriages

Frank C. Hayes, M.D., to Miss Lucy Yarborough, both of Camden, Ill., November 9.

Robert C. Hogue, M.D., to Miss Blanche Reebols, both of Norfolk, Va., November 17.

Charles Elliotte Howard, M.D., to Miss Nettie Schmidt, both of Cincinnati, November 23.

Leo A. Parker, M.D., Brooklyn, N. Y., to Miss Helen L. Phelan, at Brooklyn, November 16.

Lewis D. Remington, M.D., to Mrs. Cassie A. Matthews, both of Monrovia, Cal., November 16.

Edward J. Thayer, M.D., to Miss Florence E. Reynolds, both of New York City, November 21.

William H. Schmidt, M.D., Atlantic City, to Miss Mary Grace Clark of Philadelphia, November 23.

Noel C. Womack, M.D., Jackson, Miss., to Miss Jean McLaurin, of Brandon, Miss., November 15.

John Scott Willock, M.D., Pittsburg, Pa., to Miss Anne Elizabeth Bowes, of Baltimore, November 15.

Bonaparte P. Norvell, M.D., Muskogee, Okla., to Miss Bessie Carter, of Palmyra, Mo., November 14.

Charles Thomas Pyles, M.D., Hancock, Md., to Miss Mary Elizabeth Griffith, at Poolesville, Md., November 16.

Robert French Compton, M.D., Charlottesville, Va., to Miss Mary Barbour Rixey, at Charlottesville, November 8.

Charles Victor Haggman, M.D., Concordia, Kan., to Miss Clementine Creager, of Kansas City, Mo., November 12.

George Sheldon Adams, M.D., Yankton, S. Dak., to Miss Valborg S. Smith, of Dell Rapids, S. Dak., November 10.

Granville Hampton Richards, M.D., Port Deposit, Md., to Miss Mary Emma Wright, at Baltimore, November 16.

John Stanley Coulter, M.R.C., U. S. Army, Washington, D. C., to Miss Helen Miller, of Mount Airy, Pa., November 21.

Deaths

James Ross Waggener, M.D. Jefferson Medical College, 1872; a member of the American Medical Association; medical director, U. S. Navy, retired; died in the Corry Hill Hospital, Brookline, Mass., November 17, aged 64. Dr. Waggener entered the United States Navy in 1872, and after thirteen years sea service and sixteen years and two months shore or other duty, was retired as medical director, May 6, 1907, on account of incapacity resulting from an incident of service. He served from 1875 to 1877 in the Naval Hospital, Norfolk, Va., was made passed assistant surgeon in 1875, surgeon in 1887, and attained the rank of captain in 1903. During the Spanish-American War he was attached to the Mare Island Navy Yard, and later was on duty at the Naval Hospital, Cavite, P. I.

Edmund W. Stevens, M.D. Jefferson Medical College, 1884; a member of the American Medical Association, American Ophthalmological Society and American Academy of Ophthalmology and Oto-Laryngology; president of the Denver County Medical Society in 1907; ophthalmologist to the Denver County, St. Anthony's and Mercy hospitals; formerly instructor in diseases of the eye in the Philadelphia Policlinic; died at his home in Denver, October 30, from nephritis, aged 47.

James C. Nidelet, M.D. Missouri Medical College, St. Louis, 1860; surgeon in the Confederate service during the Civil War; one of the founders and for several years professor of anatomy and dean of the faculty of McDowell Medical College, St. Louis; for four years a member of the board of police commissioners, and for two years vice-president of the board; died at his home, November 15, from heart disease, aged 76.

George S. Stein, M.D. University of Pennsylvania, Philadelphia, 1864; a member of the American Medical Association and Mississippi Valley Medical Association; assistant surgeon, U. S. Army during the Civil War; professor and emeritus professor of genitourinary diseases in the Ohio Medical University; died at his home in Columbus, November 19, from heart disease, aged 68.

Robert Gildea O'Hara, M.D. College of Physicians and Surgeons, Baltimore, 1885; formerly an officer in the English service; a member of the Medical Society of Virginia; physician for the Elks' National Home; and chairman of the board of health of Bedford City; died in St. Andrew's Hospital, Lynchburg, November 13, from heart disease, aged 54.

Leslie James Meacham, M.D. Cornell University, New York City, 1902; formerly a member of the American Medical Association and of the New York Academy of Medicine; visiting physician and psychotherapeutist to the Cornell Dispensary, Department of Neurology; died in New York City, October 23, from paresis, aged 50.

John J. Smith, M.D. Long Island College Hospital, Brooklyn, 1891; a member of the Washington State Medical Association; a member of the state legislature in 1899, and of the state senate in 1901, and chosen president of the latter body in 1903; died at his home in Enumclaw, November 12, from typhoid fever, aged 41.

Henry Heidelberg, M.D. St. Louis College of Physicians and Surgeons, 1891; member of the American Medical Association; and president of the Monroe County Medical Society; died at his home in Hecker, Ill., July 2, from cirrhosis of the liver, aged 40.

John Danforth Woodworth, M.D. Rush Medical College, 1852; formerly president, supervisor and member of the school board of Leslie, Mich.; a member of the legislature in 1860; and surgeon of volunteers throughout the Civil War; died at his home in Leslie, November 7, from senile debility, aged 85.

Theodore Rudolph Burgtorf, M.D. Eclectic Medical College of the City of New York, 1891; Long Island College Hospital, Brooklyn, 1894; a member of the Medical Society of the State of New York; was shot and killed by his mentally-deranged wife at his home in New York, November 14, aged 55.

Fred W. Inman, M.D. University of Michigan, Ann Arbor, 1864; a pioneer manufacturer of cereals; one of the founders and president of the *Florida Citrus Exchange*; a surgeon in the army during the Civil War; died at his home in Winter Haven, Fla., November 6, from cerebral hemorrhage, aged 70.

Lutellus Lindley Porter, M.D. Medical College of Ohio, Cincinnati, 1869, a member of the American Medical Association, for many years mine physician and local surgeon of the Northern Pacific Railroad at Roslyn, Wash., died at his home in North Yakima, Wash., November 15, from cancer, aged 63.

Thomas Robinson Little, M.D. University of Pennsylvania, Philadelphia, 1900, a member of the American Medical Association, medical director of the Southern Life and Trust Company, died at his home in Greensboro, N. C., November 15, from the effects of an overdose of morphin, aged 36.

William Forrest Gatchell, M.D. George Washington University, Washington, D. C., 1891, a member of the Medical Association of the District of Columbia, formerly chief clerk of the Steamboat Inspection Service, died at his home in Washington, November 16, from nervous prostration, aged 51.

Joseph Adams, M.D. Western Homeopathic College, Cleveland, 1859, M.C.P. & S., Ont., 1869, a member of the Council from 1869 to 1875, and a member of the Board of Examiners in 1880, Chicago Homeopathic Medical College, 1882, died at his home in Toronto, September 26, aged 85.

Joseph Francis Finn, M.D. College of Physicians and Surgeons, New York City, 1854, first county physician of Hudson County, N. J., a member of the Board of Education of Jersey City from 1899 to 1901, died at his home in Jersey City, November 19, from acute gastritis, aged 77.

James E. Thompson, M.D. Baltimore University, School of Medicine, 1897, died at his home in Throop, near Scranton, Pa., September 18, from the effects of a bullet wound of the head, believed to have been self inflicted with suicidal intent while suffering from melancholia.

Charles W. Rodgers, M.D. University of Virginia, Charlottesville, 1886, a member of the Medical Society of Virginia, for many years a member of the State Board of Medical Examiners, died at his home in Staunton, November 15, from tuberculosis, aged 48.

Albert M. Clinkscales, M.D. Jefferson Medical College, 1877, a member of the American Medical Association, formerly president of the Indian Territory Medical Association, died at his home in Vinita, Okla., November 17, from cerebral hemorrhage, aged 55.

Chester L. Stewart, M.D. Berkshire Medical College, Pittsfield, Mass., 1851, since 1893 president of the Board of Pension Examiners of Randolph, Vt., where he had practiced for fifty-six years, died at his home, November 16, from heart disease, aged 81.

George Sanford Post, M.D. Albany (N. Y.) Medical College, 1899, of Holley, N. Y., a member of the Medical Society of the State of New York, died in the City Hospital, Rochester, October 25, from general septicemia following appendectomy, aged 38.

Alfred Alfonso Harper, M.D. Baltimore Medical College, 1902, a member of the American Medical Association, a member of the board of health of North Adams, died at his home in that city, November 14, from rheumatic arthritis, aged 34.

William F. Waite, M.D. University Medical College, Kansas City, Mo., 1893, a veteran of the Civil War, and a clergyman of the Christian Church, once city physician of Kansas City, Kan., died at his home in that city, November 11, aged 62.

William Francis Shine, M.D. Tulane University, New Orleans, 1858, of St. Augustine, Fla., surgeon in the Confederate army during the Civil War, assistant surgeon U. S. Army, died in the Flagler Hospital, St. Augustine, October 21, aged 71.

Samuel M. Ried, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1878, a member of the Indiana State Medical Association, for ten years health officer of Muncie, Ind., died at his home in Muncie, November 7, aged 68.

James Edgar Sawdon, M.D. Trinity Medical College, Toronto, 1902, M.R.C.S., Eng., and L.R.C.P., Eng., 1908, formerly of Blind River, Ont., but later of Listowel, Ont., died at his home in that place, August 30, from small pox.

Jesse B. McBride, M.D. University of Pennsylvania, Philadelphia, 1865, a surgeon during the Civil War, for many years a resident of Columbia, Pa., died at his home in Washington, D. C., October 27, aged 68.

Joseph R. Whalen, M.D. Louisville Medical College, 1894, demonstrator in anatomy in his alma mater for a year thereafter, died at his home in Carlisle, Ind., November 10, from cerebral hemorrhage, aged 49.

Hanford Benedict (license, Ind., 1897), a member of the Michigan State Medical Association, for three terms postmaster of Springport; died at his home, November 6, from cancer of the liver, aged 73.

Harry W. Bradley, M.D. Detroit College of Medicine, 1909; a member of the Saginaw County Medical Society; died at the home of his parents in Saginaw, Mich., November 16, from typhoid fever, aged 25.

John Wesley Willis, M.D. Meharry Medical College, Nashville, 1902, a colored practitioner of Bowling Green, Ky., died suddenly in a church in that city, October 30, from cerebral hemorrhage, aged 42.

Stiles R. Fox (license, Ind., years of practice, 1897), for thirty-five years a practitioner of Lafayette, Ind., died at St. Elizabeth's Hospital in that city, November 16, from cerebral hemorrhage, aged 62.

Robert Dunlop, M.D. Hospital College of Medicine, Louisville, 1884, for many years physician to the Little Sisters of the Poor, died at his home in Louisville, November 9, from uremia, aged 57.

James Richard Sowers, M.D. George Washington University, Washington, D. C., 1859, a Confederate veteran; died at his home in Warrenton, Va., November 13, from cerebral hemorrhage, aged 73.

William G. Hart, M.D. Vanderbilt University, Nashville, 1877, a member of the State Medical Association of Texas, died at his home in Gordon, November 15, from cerebral hemorrhage.

Henry W. Boorn, M.D. Albany (N. Y.) Medical College, 1866, a member of the Medical Society of the State of New York, died suddenly at his home in Schenevus, November 8, aged 70.

Benjamin Franklin Lisk, M.D. (license, Fla., 1885); of Grahamville, drove into the Ocklawaha River, at the ferry near Grahamville, November 7, and was drowned, aged 73.

James Columbus Ozee (license, Ill.), for thirty-five years a practitioner of Illinois, died at the home of his brother in Mattoon, November 2, from cerebral hemorrhage, aged 69.

Herbert George Chislett, M.D. *Hahnemann Medical College*, Chicago, 1903, of Berwyn, Ill., died in the Hahnemann Hospital, Chicago, November 22, from pneumonia, aged 44.

Daniel Wayland Jones, M.D. New York University, New York City, 1852, a member of the American Medical Association, died at his home in Boston, November 7, aged 81.

William H. Nichols, M.D. Albany (N. Y.) Medical College, 1867, for forty-three years a practitioner of West Sand Lake, N. Y., died at his home in Troy, N. Y., October 31.

J. D. Orr, M.D. Atlanta (Ga.) Medical College, 1878, a member of the South Carolina Medical Association; died at his home in Spartanburg, November 6, aged 52.

Ulysses G. Talley, M.D. Meharry Medical College, Nashville, 1896, a well known colored practitioner of New Orleans; died at his home in that city, November 3, aged 38.

Joseph L. Taylor, M.D. Eclectic Medical Institute, Cincinnati, 1873, died at his home in Logansport, Ind., November 13, from acute gastritis, aged 71.

Charles William Clough (license, years of practice, Mass.); a practitioner since 1888, died at his home in Conway, Mass., November 16, from nephritis, aged 73.

Henry Wheelock Browne, M.D. Harvard Medical School, Boston, 1856, died at his home in Hubbardston, Mich., November 8, from heart disease, aged 78.

Abraham Virgil Conklin, M.D. Eclectic Medical Institute, Cincinnati, 1860, died at his home in Delaware, Ohio, October 28, from pneumonia, aged 77.

John R. Chatham, M.D. Washington University, St. Louis, 1873, died at his home in Tamms, Ill., November 13, from cerebral hemorrhage, aged 68.

John R. McCauley, M.D. College of Physicians and Surgeons, St. Louis, 1891, died at his home in Sulphur Springs, Tex., October 31, aged 57.

Richard K. Gregory, M.D. New York University, New York City, 1860, died at his home in Greensboro, N. C., September 10, aged 74.

Charles J. Ramsey, M.D. Southern Medical College, Atlanta, Ga., 1891, died at his home in Roswell, Ga., November 2, aged 42.

William Henry *Graham, M.D.* *Toronto School of Medicine*, 1871, died at his home in Toronto, June 21, from pneumonia, aged 61.

Pharmacology

RADIO-SULPHO CANCER CURE

"A Bad Smell Capitalized for a Million Dollars"

Of "cancer cures" there seems no end. One of the latest humbugs in this line is known as "Radio-Sulpho" and is sold by the "Radio-Sulpho Company," of Denver. The company is incorporated for $1,000,000 and has for its "consulting physician," E. H. Griffith, M.D., and for its president, one Philip Schuch, Jr., who modestly describes himself as a "chemist and cancer specialist."

Mr. Schuch, Jr., says that he has discovered that the vaccine used in vaccination is the cause of cancer and, further, that he is "able to culture the cancer germs direct from the vaccine." Schuch, Jr., "cures" cancer by means of a combination of "Radio-Sulpho," "Radio-Sulpho Brew" and Limburger cheese. This is not a joke but a "method" recommended by the Radio-Sulpho Company.

Incidentally, Schuch, Jr., has recently leaped into the limelight of newspaper publicity by proposing to introduce at the coming session of the Colorado legislature a bill making it a penal offense to perform an appendicectomy on any but a diseased appendix. Mr. Schuch's love for the medical profession has waned, apparently, since the State Board of Health of Colorado condemned his odoriferous "cancer cure," saying that it is "misbranded, of no medicinal value and that it contains sewer gas."

The patient is instructed to wash the cancer with dilute Radio-Sulpho solution and then apply the "cheese poultice." The poultice is to be made by taking one pound of "real imported" Limburger cheese and kneading it thoroughly with five ounces of pure glycerin. The poultice and washing are to be renewed every twelve hours. Says Mr. Schuch, Jr.:

> "A person that has a weak constitution . . . should never use the Limberger [*sic*] cheese for a poultice, as it is too powerful a magnet. A person must be robust and healthy, aside from the cancer, to stand the powerful drawing of Limberger [*sic*] cheese, prepared as described."

This statement is certainly the most—and possibly the only—conservative one in the booklet which is sent out by the concern. The mere thought of plastering a sick person with such an indescribably nauseating mess as Limburger cheese and glycerin is enough to sicken one. Nor is this all! The nostrum itself has as vile an odor as the cheese. In fact, it reeks with sulphuretted hydrogen (the gas which imparts the distinctive odor to rotten eggs) and the state chemist of Colorado has aptly characterized the nostrum as "a bad smell capitalized for $1,000,000."

The Radio-Sulpho Brew is to be taken internally at the same time that Radio-Sulpho is used as a "wash." Both these products were analyzed by the Colorado State Board of Health, and the state chemist, Dr. E. C. Hill, reports as follows:

> "Radio-Sulpho itself consists of a strongly alkaline solution of sodium sulphid, with a little sodium carbonate and a decided odor of hydrogen sulphid (made presumably by heating together sulphur and commercial caustic soda in water).
>
> "Radio-Sulpho Brew is a weakly alcoholic solution of Epsom salts disguised with a bitter vegetable."

The cost of this evil-smelling treatment is $25.00 a month "and upward." Victims are told that "cancer of the womb and breast are the simplest, easiest and quickest cures made." Schuch, Jr., who apparently has no medical education and no legal right to practice medicine, states in his booklet: "I treat personally the white race only." His charges are: "$100.00 per day or part of a day and all railroad expenses *going* to points east of the Mississippi, or west of Salt Lake, Utah. . . ."

An absurd falsehood, even for a nostrum concern whose stock-in-trade is deceit, is found in the booklet:

> "When you buy our remedies at the prices we herein quote you, you are not paying the FULL COST of the manufacturing and the marketing of the remedies. You are only paying your share, and I, as a philanthropist, bear the remainder and the greater burden."

The thought of a million dollar quack organization selling its products at a loss would be amusing, if the business it is in were not such a cruel and heartless one. Of course those who are desperately or incurably ill with cancer will grasp at any straw, however worthless or dangerous. But that the physical suffering and mental anguish of these unfortunates should be increased by the barbarous malpractice of "cancer cure" fakers and by the blasting of hopes falsely raised, is an outrage that civilized communities should not tolerate.

CHINOSOL—A CORRECTION

One of the most valuable pieces of original pharmacologic work done recently was that reported by Post and Nicoll in THE JOURNAL, Nov. 5, 1910. In general these experimenters showed that the efficiency of many germicides—proprietary and others—in common use, and for which broad claims are or have been made, is as a matter of fact practically *nil.* But in publishing the results of this work, THE JOURNAL unwittingly did the manufacturers of one of the products dealt with an injustice. Among the various preparations with which the investigators experimented was the proprietary antiseptic chinosol. This product was taken up with the others, because, at the time the experiments were made and the article was written, chinosol was advertised and sold as a germicide. In the interim between the acceptance of Drs. Post and Nicoll's article and its publication, however, the Council on Pharmacy and Chemistry proved to the satisfaction of its manufacturer that chinosol is but a very indifferent germicide, although it is an exceedingly powerful antiseptic. As chinosol has not for some time been advertised or sold as a germicide reference to that product should have been deleted from the article in question before publication, but by an oversight, the responsibility for which THE JOURNAL accepts, this was not done. With the present confused ideas on the subject of germicides and antiseptics and the very general misconception that there is little difference between these two classes of products, it is well to call attention to the fact that although a preparation may have little value as a germicide it can still be a powerful and useful antiseptic.

Correspondence

Opportunities for Physicians in Mission Lands

To the Editor:—Thirty vacant fields for medical men and twenty-two for medical women, with no competition and unlimited opportunities for original research, have been brought to my attention by various missionary societies. Some hospitals have had to be closed for lack of workers.

For men with pioneer instincts, there are great fields entirely unoccupied, while for expert surgeons there is work at hand which is already self-supporting. Several internships, from one to three years, are also open for recent graduates.

For women to whom the experience of Dr. Susie Rijnhart, of Thibet, appeals, there are great fields entirely unoccupied, while for experienced surgeons there are hospitals waiting.

All this work is under the missionary societies of the various Protestant churches of the United States and Canada.

The work requires men and women of good health and rugged constitution, not over 35 years of age, graduates of first-class medical schools (in some instances only those who have had both collegiate and professional training, together with either postgraduate or hospital experience), members of some Protestant church, and definitely interested in the religious motives and purpose of medical missions.

Comfortable support is provided by the missionary societies. This includes traveling expenses for physicians and their families, provision for outfit, living quarters, language teachers, etc., in addition to which a salary is paid which is based on what experience shows to be needed to maintain the worker in the highest state of efficiency. This varies in different countries. The net result is the same. It is not a work which will attract one who seeks large financial returns. The work demands those of heroic mold, who want to find the place where their medical skill is needed and where all their training will be utilized to the utmost. The work demands devotion, wide sympathy and earnest purpose. From a purely professional standpoint, these opportunities are unparalleled. A woman graduate of a Canadian university, who went to Arabia a few years ago, reported after a fortnight in the only hospital along the coast of a thousand miles. 'During my visit here we have had twenty operations on the eye, one amputation, the removal of a large tumor and numerous teeth extracted. In medicine we have had pleurisy, tuberculosis, tetanus, small pox, leprosy, paraplegia, different varieties of heart lesions and other interesting cases. In gynecology we have the usual run of inflammations and displacements, with atresia for a specialty. One of the peculiarities of the people here is that they never present themselves for treatment until the disease is far advanced, but of course there is an excuse for them in some cases, as they may have suffered for years before there was a hospital to come to. About 75 per cent. of the people seem to have eye trouble of some sort. Trachoma, trichiasis, ulceration and opacity are the commonest forms, yet inside a week one meets everything from simple ophthalmia to panophthalmitis. In fact, one would have to be a specialist in every branch of medicine and surgery to do justice to the amount and range of material."

Calls are now in my hands from great cities, as well as country districts of China, Africa, Persia, the Philippine Islands, Egyptian Sudan, Arabia, Mexico, Turkey and Korea.

I shall be glad to give further details to any physician to whom this opportunity for service appeals.

WILBERT B. SMITH,
Acting Candidate Secretary, Student Volunteer Movement,
125 East Twenty-Seventh Street, New York City.

Dr. Shepard and the Turkish Bath

To the Editor:—The death of Dr. Charles H. Shepard of Brooklyn, Oct. 29, 1910, deserves more than a passing notice, from the fact that he was literally the founder and promoter of the Turkish bath movement in this country. He was born in Ogdensburg, N. Y., Sept. 25, 1825, and received a medical degree from the New York Medical College in 1848. In 1861 he opened, on a broad scientific basis, the first Turkish bath in America, at Columbia Heights, Brooklyn, and of this he continued in active charge up to the time of his death.

He was a member of the American Medical Association and was secretary in 1893 and 1894 and chairman in 1895 of the section now designated the Section on Preventive Medicine and Public Health. For many years he contributed articles to this Section and was one of the earliest writers in this country on the medical use of water, particularly in the form of Turkish baths. Some of his papers were translated abroad and were widely circulated as graphic presentations of the value of baths in various diseases.

In 1876 he treated a case of hydrophobia with success at the Turkish bath, and this at the time attracted considerable attention, and was the subject of many theories and discussions. Dr. Shepard was one of the first men in this country to write with great positiveness on toxemias as active causes of disease, and he urged the elimination of toxic products through baths. Many of his early papers on this subject were practically forerunners of a literature that is growing constantly.

Dr. Shepard visited all the old and new baths of Europe, and made some studies of the Turkish and Roman baths, which were embodied in lectures and papers that were highly appreciated at the time. At one time he knew every bath in America as well as in Europe, and what was being done there, and was an adviser to the managers. His persistent efforts urging the use of the baths has brought them into popularity in all large sanatoriums and in some insane asylums.

It is understood that Dr. Shepard left a large mass of manuscript on the Turkish bath and on his experience of over fifty years, which will be published in the future. He died from heart failure, after a short period of invalidism, and his body was cremated, according to his wish.

T. D. CROTHERS, M.D., Hartford, Conn.

Electricity in Poliomyelitis

To the Editor:—Dr. Theodore Diller, *commenting on Dr. B. Sach's paper of October 22*, takes up the treatment of electricity (THE JOURNAL, Nov. 5, 1910, p. 1663), and condemns its use in poliomyelitis. If other medical colleges teach as much about electricity and its medical uses as the one I attended their graduates had something to learn after leaving college. I wish to protest against the condemnation of this most useful agent, which at times gives almost magical results even when abused in its use. If one forgets the dose of a medicament or takes up one with which he is unfamiliar, he looks in a "dose" book and prescribes accordingly. If the drug is a liquid it is usually dissolved in an alcoholic solution (and alcohol has been known to make people forget they ever had a pain).

When it comes to the use of electricity, either medicinally or commercially, there is more than one modality. In medicine the induced (faradic) current, the continuous (galvanic) current, given first direct and then make and break on the opposite pole, the static breeze and sparks, during the administration of which the little patient can be held in the nurse's arms; the motor wave current, then the high frequency or step up voltage from either the static or coil, give results that can be seen day to day.

Massage stimulates the nerves where they are kneaded; braces imprison already enervated muscles and thus diminish their size and use; transplantation of nerves or muscles helps in some instances. To use electricity requires time and patience, and if those who have neither of these condemn its use indiscriminately it shows lack of something. The fact that there are so many veiled references to it in literature is proof enough that there is virtue in the use of electricity.

The proper way to ascertain its value for definite presentation would be for the American Medical Association or the American Electrotherapeutic Association to appoint a committee to which scientists outside of medicine could furnish evidence and data not obtainable by the medical man and that would be authoritative.

ALMERIN W. BAER, PH.G., M.D., Chicago.

The Nasal Spatiometer: A Suggested Name for Dean's Septimeter

To the Editor:—I have just read with interest an article in THE JOURNAL (Nov. 26, 1910, p. 1858) by Dr. L. W. Dean, on "Changes in the Nose After Widening the Palatal Arch." It seems to me that Dr. Dean would attract more attention to his septimeter and to his particular line of investigation were he to give his instrument another name. There are septometers on the market. In fact, I described a nasal septometer in the *New York Medical Journal*, July 13, 1901. A nasal septometer is an instrument devised to measure the nasal septum, its thickness at any point. Dr. Dean's instrument was designed to measure, not the septum, but the distance between the septum and the turbinate bone; it might just as well be called a turbinometer. Now were he to name his instrument a "nasal spatiometer" he would more definitely describe the use of his device. The coined word is derived from the Latin words, *spatium*, "a space or distance," and *metrum*, "a measure." I think that Dr. Dean is entitled to differentiate his new device from an instrument that has been on the market for years.

HENRY WALLACE, Glen Ridge, N. J.

Phenol in Herpes

To the Editor:—For the past four years I have treated herpes with an application of a 95 per cent. solution of phenol. As soon as the skin begins to turn white I neutralize the phenol effect with alcohol. In many cases one application suffices; in no case is it necessary to make more than three applications. After one application of the 95 per cent. phenol I dress the lesions with a simple ointment like zinc oxid. It is surprising how quickly it will relieve the pain, itching and burning. The vesicles shrivel and dry up in a very short time leaving a dry crust. I first used it in herpes progenitalis with such satisfactory results that I was led to try it for herpes zoster, in which it gave equally satisfactory results. Looking over the literature of herpes, I have not been able to find phenol mentioned in its treatment.

G. P. COOPERNAIL, Bedford, N. Y.

USE OF THE WORD 'NUTRIANT'

To the Editor —In reading the recent edition of Wood's "Therapeutics,' pp 12 and 283, I came across the word "nutriant" I fail to find this word in any of the dictionaries at hand Is it a recognized word, and if so, what does it mean? Or is it a mistake for 'nutrient' ? Medicus, Baltimore

Answer —We do not find 'nutriant recognized by any authorities on the English language The word "nutriant," of course, could not be derived directly from the verb *nutrire*, the present participle of which is *nutriens*, from which we get 'nutrient " The only verb from the same root as *nutrire* given in Harper's Latin Dictionary is *nutricare*, 'to suckle, nourish, support, sustain," present participle *nutricans* The word "nutriant' appears to be applied by Wood, not to substances which nourish—nutrients—but to substances which increase nutrition A word with this meaning would be a useful addition to the English language, but "nutriant," since it differs from "nutrient" by only the vowel of the last syllable, has the disadvantage that it would be taken for a misprint for the latter in nine cases out of ten

Dr Horatio C Wood Jr, in reply to our letter regarding the matter, writes "This word was coined many years ago to signify drugs which affect the metabolic, or nutritive, processes The ending 'ant' was chosen to be in harmony with such terms as cardiant,' 'expectorant 'eliminant,' 'digestant,' etc I recognize the force of your statement, that the word is so nearly like 'nutrient as to lead to possible confusion, but it has been employed for nearly twenty years and the present instance is the first which has come to my notice of any uncertainty as to its meaning"

The Public Service

Medical Corps, U. S. Navy

Changes for the week ended Nov 26, 1910

Brister, J M, surgeon, detached from the naval academy and ordered to duty at the naval hospital, Annapolis, Md

Fauntleroy, A M surgeon, detached from the naval hospital, Philadelphia, and ordered to the *Solace*

Iden, J H surgeon, detached from the naval hospital, Annapolis, Md, and ordered to the *Washington*.

Field, J G, surgeon detached from the *Washington* and ordered to Washington, D C, for examination for promotion and to await orders

Allen, A H, P A surgeon detached from the naval hospital, New York, and ordered to the *Washington*

Robnett, A H, P A surgeon, detached from the naval recruiting station, Cedar Rapids, Iowa, and ordered to the marine corps rifle range, Winthrop, Md

Board of medical officers convened to meet at the marine hospital, Port Townsend Wash, Nov 21, 1910, for the purpose of making a physical examination of an officer of the Revenue Cutter service Detail for the board Surgeon P M Carrington, chairman, Surgeon J. H Oakley, recorder

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

INFANT MORTALITY AND BIRTH REGISTRATION

One of the most important reports presented at the recent meeting of the American Association for the Study and Prevention of Infant Mortality was that of the Committee on Birth Registration, consisting of Dr Cressy L Wilbur, chairman, Dr Wilmer R Batt, Pennsylvania, Dr Charles V. Chapin, Rhode Island; Dr John S Fulton, Maryland; Dr. John N. Hurty, Indiana, and Dr. William C. Woodward, District of Columbia The committee stated that study and knowledge of infant mortality should precede efforts for the prevention of such mortality, since the nature and exact extent of the causes of infant mortality must be understood before the most effective means could be used for its prevention, or the efficiency of the various agencies employed be measured While it is not necessary to consult a table of statistics to know that filthy, bacteria-teeming milk should not be used for infants, and while no statistics are necessary for the prevention of mortality from intestinal diseases in infants, yet our knowledge of the prevalence of these diseases has resulted from thorough registration of births and deaths. If the American Association for the Study and Prevention of Infant Mortality is to lead in the saving of infant life, it must have vital records by which its success can be measured, and it is therefore, one of the paramount duties of the organization to support all efforts for better vital statistic legislation What is needed is a series of accurate figures regarding infant mortality for cities, rural districts, states, and the nation as a whole They should be reliable, up to date, and presented in such form as to be comparable among themselves and with those of foreign countries. A thorough analysis of the returns should be made with regard to the cause of death, nativity, occupation of parents, sanitary condition of dwellings etc The first step is to secure complete and comparable data for the entire infant mortality, adding other details later Accurate statistics regarding infant mortality require the registration of both births and deaths, since infantile mortality is the ratio of the number of deaths of infants under one year of age to 1,000 children born alive, and not to the estimated population of that age. True infantile mortality can not be computed from the registration of deaths alone unless the birth rate is also known. Consequently, under existing conditions, it is impossible to present reliable statistics of infantile mortality for the United States, for any single state, or even for a single large city in the entire United States The present registration area includes only 55 3 per cent of the total population, as many states, including practically the entire South, make no record of deaths of their citizens, while even those states that have fairly good death registrations, grossly neglect birth registration. As an illustration of the importance of birth registration, the committee report quotes from the graphic examples cited by Dr. J. N Hurty, in his chairman's address before the Section on Preventive Medicine and Public Health.[1]

The committee discusses the duties of physicians and midwives in registering births, holding that they are not charged with the enforcement of the registration laws, but that it is their duty to obey these laws and that if they do not obey them, it is the duty of the registration officials to compel them to obey, under penalty of the law. Not even in New York City are the birth records complete, according to the local department of health, "there being still many that are not recorded by reason of the neglect of medical attendants and midwives." Regarding other cities, the report continues: 'It is a little difficult to decide in which of these great and prosperous cities of the United States—Baltimore, Chicago or New Orleans—the registration of births is most utterly worthless, but it is certain that it would not be possible to find their equals for worthlessness in any other country where vital records are maintained."

The remedy proposed by the committee is the enactment of adequate laws for the complete registration of births and deaths and the thorough enforcement of these laws After discussing the model law endorsed by the American Medical Association, the American Public Health Association, the Bureau of the Census and other bodies, the experiences of Pennsylvania, Ohio, and Missouri under this law are reviewed. At present, while the registration area for deaths is being rapidly extended, the registration of births is confined to a very few states and even these have only an approximate registration of 90 per cent. The New England states, Michigan, and the District of Columbia have fairly satisfactory birth registration laws, but Pennsylvania is to day the only state in which a determined effort has been made to secure complete registration of all births. In the great majority of states the law (where one exists) is practically a dead letter with the result that birth statistics and figures for infant mortality are both practically worthless.

The committee utters a warning against needless tampering with vital statistics laws or forms of registration and urges that no change be made in the model law or in the blank certificates, during the next ten years. Much of the imperfection of what vital statistics we have is due to the absence of a uniform blank for the initial data. This defect has been remedied by the adoption of standard certificates and any alteration should be discouraged until the defects assume sufficient importance so that the next general revision can include them, and all of the registration states can adopt them at the same time. In the words of the report: "We want no more tinkering with the forms in use until the time arrives for a general change." The vital statistics registration laws of England are reviewed and conditions there compared with those in this country. In the opinion of the committee, "It is unfortunate that the question of compensation to physicians and midwives should be urged by the medical profession in connection with the legislation for the registration or notification of vital statistics, because it at once places the profession in the position of asking a favor for interested motives, and may be denounced as 'medical graft' by many members of state legislatures It retards the cause of registration, has no good effect whatever on the completeness of the returns, and interferes with the thorough enforcement of the law." The committee also emphasizes the necessity for greater precision in terminology and for the adoption of a uniform nomenclature.

The conclusions of the committee were embodied in a preamble and resolution, which were unanimously adopted by the Association:

> Whereas, The registration of all births and of all deaths is most essential for the study of infantile mortality and the prevention of the deaths of infants and children from avoidable causes; therefore, be it
>
> *Resolved*, That the American Association for the Study and Prevention of Infant Mortality cordially approves of the model law for the registration of births and deaths, as recommended by the American Medical Association, the American Public Health Association, and the United States Bureau of the Census, and urges the thorough enforcement of such laws by the officials charged with the responsibility of their execution, with prosecution of physicians and midwives who neglect their duties to their clients and to the public health by failing or neglecting to register births as required by law.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR JOHN H BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course]

Fourth Month—Fourth Weekly Meeting

INJURIES OF THE SPINE

Fractures, Fracture-Dislocations and Simple Dislocations of the Spine

Classification—Bryant and Buck: Am. Practice of Surgery, vi.

1. Isolated Fractures of Spinous and Transverse Processes, and Laminæ: Frequency, location, diagnosis.
2. Fracture of Atlas and Axis: Pathology, symptoms, diagnosis.
3. Bilateral Isolated Dislocations: Location, pathology, diagnosis.
4. Unilateral Dislocations: Frequency, location, pathology, symptoms.
5. Isolated Fractures of Vertebræ: Pathology, diagnosis.
6. Complete Fracture-Dislocations: Pathology, symptoms.

Symptoms of Fractures of the Spine in General: Crepitus, deformity, unconsciousness, paralysis, anesthesia, pain, priapism, delirium, cystitis, bedsores, sphincters. Regional diagnosis, symptoms of injury to cord in cervical, dorsal and lumbar regions

Treatment of Fractures of the Spine in General: Expectant treatment. Reduction and fixation of bony points. Primary laminectomy. Secondary laminectomy. Indications for each; technic of laminectomy.

Monthly Meeting

Surgery of the Spine

Diagnosis and Treatment of Fracture-Dislocation of the Spine.
Early Diagnosis and Treatment of Tuberculosis of the Spine.
Etiology and Diagnosis of Scoliosis.

State Boards of Registration

COMING EXAMINATIONS

CALIFORNIA: Los Angeles, December 6-9. Sec., Dr. Charles L. Tisdale, 929 Butler Bldg., San Francisco.

DELAWARE: Regular, Dover, December 13-15; Homeopathic, Wilmington, December 13-15. Secretary of the Medical Council, Dr. H. W. Briggs, Wilmington.

KENTUCKY: Louisville, December 15-17. Sec., Dr. J. N. McCormack, Bowling Green.

MARYLAND: 1211 Cathedral St., Baltimore, December 13-16. Sec., Dr. J. McPherson Scott, Hagerstown.

OHIO: Cincinnati, December 6-8. Sec., Dr. George H. Matson, State House, Columbus.

PENNSYLVANIA: Regular and Homeopathic, Philadelphia, December 6-9; Eclectic, Harrisburg, December 6-9. Secretary of the Medical Council, Dr. Nathan C. Schaeffer, Harrisburg.

VIRGINIA: Lynchburg, Dec. 20-23. Sec., Dr. R. S. Martin, Stuart.

Reappointed on Vermont Board

Dr. W. Scott Nay, Underhill, and Dr. F. H. Godfrey, Chelsea, have been reappointed by Governor Mead as members of the Vermont State Board of Medical Registration for a term of six years. Dr. Nay is the secretary.

Rhode Island October Report

Dr. Gardner T. Swarts, secretary of the Rhode Island State Board of Health, reports the written examination held at Providence, October 6-7, 1910. The number of subjects examined in was 11; total number of questions asked, 70; percentage required to pass, 80. The total number of candidates examined was 12, of whom 9 passed and 3 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Yale Medical School	(1908) 89.1; (1909)	90.7
Johns Hopkins University	(1908)	89.9
College of Phys. and Surg., Baltimore	(1909) 83; (1910)	80
Harvard Medical School	(1902) 81.2; (1909)	87.4
Tufts College Medical School	(1910)	86.2
Jefferson Medical College	(1910)	86.6

FAILED

College	Year Grad.	Per Cent.
Baltimore Medical College	(1909)	72.2
University of Maryland	(1910)	78
University of Vermont	(1910)	69.5

Wyoming October Report

Dr. J. B. Tyrrell, Acting Secretary of the Wyoming State Board of Medical Examiners, reports the written examination held at Laramie, October 26-28, 1910. The number of subjects examined in was ten; total number of questions asked, 100; percentage required to pass, 75. Only one candidate, a graduate of the University of Louisville, 1910, was examined and he passed with a grade of 83 per cent. The following questions were asked:

PRACTICE OF MEDICINE

1. Define typhoid fever, rheumatism, appendicitis and cretinism. 2. Name the principal infantile contagious diseases and outline your treatment for one disease. 3. Mention diet for child 1½ years old as you would to mother or nurse that you were instructing. 4. What are the following skin diseases: eczema, prurigo, lentigo, herpes and urticaria? 5. Mention treatment for psoriasis, erysipelas and ringworm. 6. What are mania, melancholia and dementia? 7. Describe epilepsy and give treatment. 8. Give symptoms and treatment of bronchopneumonia. 9. Give diagnosis and treatment of gastric dyspepsia. 10. What is chlorosis? Give treatment.

ANATOMY

1. Give a careful description of the duodenum, stating length, caliber and openings into it. 2. If the femoral artery were obstructed at the apex of Scarpa's triangle, through what channels would the blood flow to reach the tibial arteries? 3. Describe the structure of the knee joint. 4. Name the twelve pairs of cranial nerves. 5. Describe a hair follicle. 6. Give the course and relations of the ureters in the male; also female. 7. Name the five muscles of the back of the leg. 8. What tissues of the abdominal wall are divided in the operation for appendicitis at (a) McBurney's point, (b) over the rectus muscle? 9. Describe the course and distribution of the nerves of the palm of the hand. 10. What is connective tissue and where is it found?

PHYSIOLOGY

1. Give the physiology of the ureter. 2. Describe the nervous mechanism of muscular contraction. 3. Describe the physiologic properties of bile. 4. Describe the physiologic differences between lymph and serum. 5. What is metabolism? How many kinds and what are the differences? 6. What is food? Classify and give functions. 7. Describe briefly nervous control of heart. 8. What are the principal physiologic functions of the skin? 9. Describe the physiologic function of the testes. 10. Differentiate between serous mucus and synovial membranes. Tell where each is found.

PATHOLOGY AND BACTERIOLOGY

1. Define anemia, hyperemia, leukemia, leukopenia. 2. Name the intestinal lesions of typhoid fever and give pathology of each. 3. Differentiate between carcinoma and sarcoma and give the diagnostic pathology of each. 4. Describe method of making the Widal reaction. 5. How do bacteria multiply? 6. Name the principal characteristics that would be present in a suspected culture if it contained typhoid bacilli. 7. What is tuberculin? 8. What is the difference between an antitoxic serum and an anti-infectious serum? 9. Give pathology of scorbutus. 10. Give pathology of catarrhal appendicitis.

CHEMISTRY AND TOXICOLOGY

1. What is sp. gr.? What is a urinometer? Give specific directions for its use. 2. Describe physical and chemical changes of substances. Give examples of each. 3. Define chemical symbols. For what are the following symbols: (a) Au, (b) Ag, (c) Fe, (d) As, (e) K, (f) Sb, (g) Zn, (h) Hg? 4. Write formula for (a) common salt, (b) hydrogen dioxid (c) carbonic anhydrid, (e) calcium sulphate, (f) boric acid. 5. Write about iron; occurrence in nature atomic weight, properties, and name several of the preparations used in medicine. 6. Write about alcohol; its occurrence, formation, properties and name some of the preparations used in medicine. 7. How is iodoform made and what are its properties? 8. Give symptoms, fatal period, fatal dose and treatment of phosphorus poisoning. 9. Give symptoms, fatal period, fatal dose and treatment of acid poisoning. 10. Give test for albumin; for sugar in urine.

SURGERY

1. Name the luxations of the shoulder joints. What symptoms are common to all shoulder luxations? 2. Give etiology and symptoms of intestinal obstruction. 3. How are hernias clinically divided? Give palliative treatment of reducible hernia. 4. How are amputations classified? What general considerations are imperative to observe to insure successful amputation? 5. What are the general indications in the treatment of all wounds? 6. Describe the postoperative treatment of a case of gangrenous perforative appendicitis. 7. What are the general considerations as to the treatment of gun-shot wounds? 8. Describe case of cellulitis of hand and give treatment. 9. What is the cause of varicose veins? How should you treat them? 10. Differentiate between location of foreign body in trachea, larynx and bronchus.

MATERIA MEDICA AND THERAPEUTICS

1. Give antidotes for poisoning by belladonna, corrosive sublimate, carbolic acid. 2. What are the physiologic actions and therapeutic uses of arsenic? 3. Give physiologic action of strychnin. In poisonous doses, how does death ensue? 4. What are expectorants? How classified? Differentiate between the classifications. 5. Name the principal purposes for which diuretics are used. 6. What is ergotism? Give physiologic effects and therapeutic uses of ergot. 7. Name two principal counter-irritants. For what purposes are counter-irritants used and on what rests the basis for their employment? 8. Write briefly concerning the methods of giving enteroclysis. What are the principal medicinal substances used and for what diseased conditions is enteroclysis indicated? 9. Give the physiologic actions of ipecac and its therapeutic uses. 10. What are the principal causes for failure in the use of bacterial therapy?

GYNECOLOGY

1. What is a caruncle of the urethra? Treatment? 2. Why is gonorrhea relatively a more grave disease in the female than in the male? 3. Is ventrofixation of the uterus ever justifiable? How is the operation performed? 4. Define plastic operations as applied to gynecology. 5. When would you use the curette? Give steps of the operation in detail. 6. Give physical signs of cancer of the uterus in the early stage. What laboratory aids to diagnosis, if any, would you resort to in confirming your physical signs? 7. Diagnosis, prognosis and treatment of uterine fibroids. 8. Give in detail the method to be used in making an examination of the pelvis. 9. State size, weight, measurements and location of normal virgin uterus. 10. Write about the menopause, and give significance of that period of a woman's life.

PHYSICAL DIAGNOSIS

1. Make drawing of the anterior osseous chest wall; show outline of the heart and thoracic aorta beneath. Indicate points covering the mitral, tricuspid, aortic and pulmonary valves. 2. State the significance of prolonged expiration. Auscultation in such a case would probably disclose what adventitious sounds? 3. Why are the apices of the lungs usually first affected in pulmonary tuberculosis? 4. Define cyanosis and give the various causes. 5. Define tachycardia; give significance. 6. What are hemic murmurs as applied to the heart, and what is the cause? 7. Name and describe the essentially different sounds given by the thorax on percussion. 8. (a) What is the cause of the second or diastolic sound of the heart? (b) What is the Corrigan pulse? Give significance. (c) Define pulsus paradoxus; intermittent pulse; dicrotic pulse; digeminal and trigeminal pulse. 9. Differentiate ascites and tympanites. 10. Give physical signs and causes of general anasarca.

OBSTETRICS

1. Describe briefly the female pelvis. 2. Give the successive changes that take place in the ovum after fecundation and during its passage to the uterus. 3. What is the umbilical cord and what are its uses? 4. Describe the fetal heart sounds, give their rate and state when and where they are best heard. 5. Write about morning sickness as to when it occurs, how long it continues, cause and treatment. 6. What is eclampsia? Give treatment. 7. Name several causes of abortion. 8. Give treatment for inevitable abortion. 9. Give list of articles needed by the physician during labor. 10. What are the dangers of a breech presentation? Why? Give treatment.

Book Notices

Edema. A Study of the Physiology and the Pathology of Water Absorption by the Living Organism. By Martin H. Fischer, Professor of Pathology in the Oakland School of Medicine, Oakland, Cal. Cloth. Price, $2 net. Pp. 209, with illustrations. New York: John Wiley & Sons., 1910.

This monograph, which was awarded the 1909 Nathan Lewis Hatfield prize of the College of Physicians of Philadelphia, is a consideration of the subject of edema and certain related topics, on the basis of the author's abundant and original investigations in certain principles of colloid chemistry. It is a well-known fact that certain colloids possess a great affinity for water, and take it up in large amounts until a condition of saturation is reached. The amount of water which will be taken up varies with the nature of the colloid, and also with the composition of the aqueous solution with which it is in contact; the latter is a very important consideration, as exhibited by such a phenomenon as the great swelling of fibrin when in slightly acidulated solutions. After a study of the influence of various substances dissolved in water on the amount of fluid which various colloids and also organized tissues will take up from such solutions, Fischer applies his results to the problem of edema. He concludes that the most important factor in the excessive accumulation of fluid in living and dead tissues is the development within these tissues of excessive quantities of acids, most commonly because of defective oxidation, the acid causing the colloids to have a much greater affinity for water than is normal. This hypothesis has the virtue of much originality and in many ways it is attractive—certainly it has not been adequately considered in the past, a defect which Fischer more than corrects. With great enthusiasm this principle is made to cover pretty much everything known concerning the presence of fluids in the tissues and secretions. Possibly Fischer is correct in this, but no physiologist or pathologist can read the work without finding many places where he meets with obstacles in applying the principle to the facts with which he is familiar. Undoubtedly the author also knows of these obstacles, and perhaps he can overcome them satisfactorily, but the critical reader would find the book much more convincing if he had done so while presenting his doctrine. There is no lack of originality and inspiration in this book, as exhibited especially in the discussion of the author's experiments on hemolysis and urinary secretion, and undoubtedly the monograph is well worthy of the prize it was awarded. Nevertheless, a more analytic discussion, and a more critical attitude toward his own arguments would, in our opinion, have been more creditable to the brilliant and enthusiastic investigator.

Die spinale Kinderlähmung. Eine klinische und epidemiologische Studie Von Dr. Eduard Müller, Direktor der Medizinischen Universitäts-Poliklinik in Marburg, mit Unterstützung von Dr. med. M Windmüller, Assistenzärztin der Poliklinik. Paper. Price, 6 marks Pp. 170, with 21 illustrations Berlin: J. Springer, 1910.

This rather extensive monograph gives a complete description of the epidemiology, etiology, pathology and clinical features of acute anterior poliomyelitis as studied in an epidemic in the vicinity of Marburg. As a review of the entire subject it serves its purpose excellently, but as an original contribution it adds little to the advancement of this subject. By means of accurate reporting of all cases it was evident that the disease usually spreads by direct contact, but that in some instances it was carried by a third person, and in exceptional cases doubtful evidence seems to implicate the soil. The incubation period varied from five to ten days. The description of the clinical features of the disease is excellent. Depending on the epidemic the respiratory and gastro-intestinal types may be differentiated. The three cardinal symptoms of onset, the hyperesthesia, the hyperhydrosis and the leukopenia, form a triad that is practically never absent. Another symptom to which he calls special attention is the wakefulness at night and the soper during the day. Müller emphasizes particularly the so-called abortive cases, which he thinks are not very uncommon. The onset is just as in a typical case, but paralyses fail to develop. The reflexes are usually lost in one extremity or more. The importance of these cases lies in the fact that their true nature may not be recognized and that they may become the means of spreading the disease.

The Taxonomic Value of the Microscopic Structure of the Stigmal Plates in the Tick Genus Dermacentor. By C. Wardell Stiles. Hyg. Lab. Bull. 62, August, 1910. Paper. Pp. 72, with 134 illustrations. Washington: Government Printing Office, 1910.

Recent discoveries showing the importance of ticks as carriers of disease, not only to animals but also to man, have rendered careful study of the structure and habits of these pests of great significance for preventive medicine. In this bulletin Stiles considers the North American species, and finds that the microscopic structure of the stigmal plates is a taxonomic character of considerable importance, upon the basis of which the *Dermacentor* of this country can be divided into four groups. The Montana tick, which has been shown especially by the extensive studies of the late Dr. Ricketts, to be a means of transmission of Rocky Mountain spotted fever, is now found to be a distinct and new species (*Dermacentor andersoni*, according to Stiles), although it has been referred to in the literature of this disease as *D. occidentalis*, largely on the authority of Stiles himself. The tick which Salmon and Stiles considered identical with *D. reticulatus* of Europe is shown to represent a new species, *D. salmoni*.

In this connection some recent correspondence in The Journal (Oct. 29, 1910, p. 1574, and Nov. 26, 1910, p. 1910) from N. Banks and Dr. Stiles will be of interest.

Dust and Its Dangers. By T. Mitchell Prudden, M.D., Author of "The Story of the Bacteria," etc. Second Edition. Cloth. Price, 75 cents. Pp. 113, with 6 illustrations. New York: G. P. Putnam's Sons, 1910.

This little volume of slightly over a hundred pages in its second edition still more forcibly emphasizes the important relation of dust to the transmission of bacterial diseases, and particularly tuberculosis. In its revised form it contains the latest knowledge concerning the bearing of dust on health, inculcates the duty of preventing or getting rid of dust in private homes, public places and the streets of our cities, and outlines methods of accomplishing this end. It also protests forcibly against the dangers of the spitting habit which is the prolific source, through dust, of the spread of tuberculosis. It is of value in the education of the laity in sanitary prophylaxis.

Handbook of Regional Anatomy. By Francis C. Ford, M.D., Professor of Anatomy, Head of Department of Anatomy and Senior Demonstrator of Anatomy in the Hahnemann Medical College and Hospital, Chicago. Cloth. Price, $1.50 net. Pp. 193. Chicago: Francis C. Ford, 1910.

This book is an attempt to supply to students or others a guide in anatomy to fill a place between the purely descriptive text of the larger anatomies and the applied anatomy of the surgeon or the diagnostician, and would perhaps be of assistance to the student in the dissecting-room. The descriptive portion, however, is so meager that it really amounts to a mere enumeration of the anatomic structures to be found in each region of the body, from periphery centralward. Mechanically, the book is not up to the standard of modern book-making.

Obstetric Nursing, for Nurses and Students. By Henry E. Tuley, M.D., Professor of Obstetrics, Medical Department, University of Louisville. Cloth. Price, $1.50. Pp. 246, with 72 illustrations. Louisville: John P. Morton & Co., 1910.

Revision makes this book more than ever a practical and serviceable guide for the obstetric nurse. Some of the pictures seem to be unnecessary; for example, that showing the use of the stethoscope in listening for the fetal heartbeat. The misspelling in Figure 7 is amusing; evidently the engraver, who did not know medical terms, did the best he could in reproducing the copy for the lettering. An index and a glossary aid in making the book valuable.

History of Chemistry. By Edward Thorpe, F.R.S., Author of "Essays in Historical Chemistry," etc. Two Volumes. Vol. II, from 1850 to 1910. Cloth. Price, 75 cents. Pp. 202, with 180 illustrations. New York: G. P. Putnam's Sons, 1910.

This is a continuation of Volume I of this work and discusses the more important discoveries in chemistry and the evolution of that science during the last half century. Considerable space is devoted to the most recent advances, especially in theoretical chemistry. The book contains several portraits of the more noted chemists of this period.

Against Ordering X-Ray Examination—Admissibility of X-Ray Photographs in Evidence—Objective and Subjective Symptoms and Hypothetical Questions

The Supreme Court of Missouri, Division No 1, says, in the personal injury case of Dean vs Wabash Railroad Co (129 S W R 953), that the defendant company filed a motion asking the trial court to order that the plaintiff submit himself to an examination by a disinterested surgeon whom the court should select, and also that he submit to have *x* ray photographs made of his alleged injured parts The motion was sustained to the extent of the surgical examination, but overruled as to requiring the plaintiff to submit to the *x* ray photograph process, because the court was advised that sometimes the subjecting of a person to that process resulted in danger to him There was no error in that matter

Two *x* ray photographs offered in evidence by the plaintiff were taken by a physician who testified that he owned an *x* ray machine and was familiar with its use and operation, that he examined the plaintiff with it, taking observations of both hips After taking the negatives with his *x* ray machine, he took them to a photographer and had the pictures developed, the operation of developing and printing the pictures was done by the photographer under the supervision of the witness who understood the art, and that the pictures were correct photographs The witness further explained that it was the bone that caused the shadows in an *x* ray photograph, and pointed out certain parts of one of the pictures which showed the enlargement of the upper part of the right thigh bone, testifying that that indicated a fracture near the base of the great trochanter of the femur

It was not error to admit those photographs in evidence Even on the theory of the defendant that such a picture is, in itself, not evidence, but only serves as a memorandum to assist the expert witness in his explanation, the pictures were properly admitted in evidence, and were used to illustrate the scientific explanation of the witness The art of making photographs of the bones of a living man by use of the *x* ray is yet still more in the keeping of science than the art of common photography, but that fact only requires more care in laying the foundation for the introduction of such photographs, it does not exclude them from evidence

The defendant called some expert witnesses and propounded to them hypothetical questions based on certain objective symptoms which some of the witnesses testified they had found on physical examination of the plaintiff and on certain facts to which witnesses testified, and asked the expert witnesses their opinions as to the injury the plaintiff had received based on those symptoms and facts On cross examination the plaintiff's attorney supplemented those hypothetical questions by asking the witnesses to take into consideration, also, certain subjective symptoms to which the plaintiff had testified, and then give their opinions based on the whole case, that is, the symptoms and facts contained in the defendant's questions, together with those supplemented by the plaintiff's questions The defendant objected to the questions on the ground that subjective symptoms should not be taken into account There was no error in overruling the objection

Objective symptoms are those which the surgeon discovers from a physical examination of his patient, subjective symptoms are those he learns from what his patient tells him When a surgeon has no cause to suspect untruth or delusion, he takes what his patient says and weighs the subjective symptoms with those he has discovered and on them he bases his diagnosis and proceeds to his prescription

Why should not a surgeon when he is called as an expert witness, and asked his opinion on a hypothetical case, take into account the same character of facts that he would when called to attend a suffering patient? Objective symptoms are no more realities than subjective symptoms if both are true Objective symptoms depend for their proof as much on the candor and capability of the witness testifying in regard to them as do subjective symptoms, a witness testifying to an objective symptom is as liable to be mistaken as one testifying to a subjective symptom and perhaps more so An opinion given in answer to a hypothetical question is based on an assumption that the facts supposed are true, but at last it is for the jury to find from the evidence whether the supposed facts are proved, if the jury find that the facts are not proved they will disregard the opinion based on them

If a physician is testifying as to the condition of a patient whom he has examined, then it is proper to draw a distinction between the objective and the subjective symptoms, but when he is asked for an opinion on a hypothetical case, he must assume the truth of the one as well as that of the other

Cancer Hospital May be a Nuisance in Residence Neighborhood

The Supreme Court of Kansas approves the injunction which was granted in the case of Stotler vs Rochelle (109 Pac R 788)

The suit was brought to enjoin the establishment, in a residence neighborhood, in a building formerly used as a dwelling house, of a hospital for the treatment of patients afflicted with cancer The home of the plaintiff was 78 feet from the main building which it was proposed to use as a hospital The two houses faced in the same direction, and each had a number of windows looking toward the other Two other residences were situated about 90 feet from the hospital building, and three others at a distance of about 150 feet

Witnesses for the plaintiff who were familiar with real estate values testified that in their judgment the establishment of the hospital would cause a material depreciation in the rental and market value of the surrounding property. Several physicians expressed the opinion that there would be some danger of the communication of the disease through transmission by means of insects, and perhaps in other ways There was also evidence that offensive odors resulting from the disease itself and from disinfectants used on account of it might reach the occupants of neighboring dwellings On the other hand, there was testimony on behalf of the defendants that none of the anticipated evils had resulted from a cancer hospital formerly maintained by them under somewhat similar conditions, that under proper management there need be no offensive odors about such a place, and that cancer is not contagious or infectious

Perhaps the court may take notice of the prevailing view in the medical profession on the last proposition From the current literature of the subject it appears that while it has not been proved to the satisfaction of the profession generally that cancer can be communicated from one individual to another except by the process of grafting or transplanting cancerous tissue, competent investigators are not lacking who believe that it is of parasitic origin and in some degree infectious That theory is presented and argued at length in an address published in the *Lancet*, January 11, 1908, to which is appended a bibliographic note Results of experiments tending to support the theory are recorded in the issues of June 5, 1909, and April 9, 1910 An article in the same publication (Dec 4, 1909, pp 1709 1711) describes observations made in Paris covering a period of two years and a half which lend color to the popular belief in the existence of "cancer houses," that is, houses the occupants of which are peculiarly subject to cancer In the present state of the accurate knowledge on the subject, it is quite within bounds to say that, whether or not there is actual danger of the transmission of the disease under the conditions stated, the fear of it is not entirely unreasonable

It is of course not necessary that the use to which property is put shall be unlawful in itself in order to constitute it a nuisance in the eye of the law Whether in a given case the obligation so to use one's own property as not to injure another's has been or is about to be so far transgressed as to justify the interference of a court is a question to be determined as a matter of reason, fairness, and justice under all circumstances. The injury need not extend beyond annoyance, if in view of all the facts, it is unreasonable. For instance, offensive odors, although not injurious to health have often been held to constitute sufficient ground for injunction.

The question was not whether the establishment of the hospital would place the occupants of the adjacent dwellings in actual danger of infection, but whether they would have reasonable ground to fear such a result and whether, in view of the general dread inspired by the disease, the reasonable enjoyment of their property would not be materially interfered with by the bringing together of a considerable number of cancer patients in this place. However carefully the hospital might be conducted, and however worthy the institution might be, its mere presence which would necessarily be manifested in various ways would make the neighborhood less desirable for residence purposes not to the oversensitive alone but to persons of normal sensibilities. The court concludes that on these considerations the injunction asked for was rightfully granted. The establishment of a cancer hospital in a residence neighborhood in near proximity to dwellings may be enjoined at the instance of one owning and occupying adjacent property.

Physicians Excepted from Missouri Medical Practice Acts

The St. Louis Court of Appeals says, in State vs. Hellscher (129 S. W. R. 1035) that the act of 1901, in so many words, was limited to those who should thereafter practice who had not theretofore registered. Those who had theretofore been duly registered were excluded from the law. In other words, this statute as originally enacted in 1901, did not create a general offense on the part of all who should thereafter practice but created an offense limited to a particular class of persons, that is, those who had not been theretofore registered, who should thereafter practice without first registering with the State Board of Health. The law related to acts committed by those particular persons only, to those thereafter practicing medicine or surgery who had not theretofore been licensed as provided by law.

This court does not think that the amendment made by the act of 1907 in any manner changed this phase of the law, nor made it any the less part of the enacting clause, notwithstanding the fact that what was before in the body of the enacting section or clause now appears as attached to that clause by way of a proviso. Changing the position of the words did not change the law. Looking at what the general assembly was attempting to do and considering the matter and phraseology of the amendment of 1907, it is obvious that this arrangement was more for the purpose of avoiding awkwardness of expression, than with any intent of change in the object of the law itself, and the mere fact that what had before been in another place in the enacting section (namely, the phrase "except physicians now registered") is transposed, and appears under the designation of a proviso, has not had the effect of eliminating the words from the enacting clause itself.

It is still the intention of the act regulating the practice of medicine and surgery that its operation shall apply only to those who had not been licensed or registered as physicians or surgeons prior to March 12, 1901. Obviously the legislature by the amendment of 1907, did not intend to invalidate the registration and licenses of physicians and surgeons who had been regularly licensed and registered under the laws prior to March 12, 1901, the date of the approval of the act of 1901, any more than it had by the act of March 12, 1901, made its provisions applicable to those who had registered as physicians or surgeons prior to that date.

Another reason for the insertion of this limitation at the end of the section, instead of leaving the exception as in the original section, may have been that, as new prohibitions were inserted by the amendment, the lawmakers did not intend to leave any doubt that those new requirements were not to be made of the old physicians.

Western Surg. and Gyn. Assn., Chicago, Dec. 19-20.

SOUTHERN MEDICAL ASSOCIATION

Fourth Annual Meeting, held at Nashville, Nov. 8-10, 1910

(Continued from page 1920)

Inguinal Hernia

Dr. John Smyth, New Orleans, reported three cases. The sac in the first case was probably a variety of the pantaloon sac. This kind of sac may account for some of the failures to cure hernia by operation. The condition in the second case was evidently the result of a failure securely to close the neck of the sac in a previous operation. The condition in the third case was the result of an effort at reduction of the hernia, in which the position of the testis was lost sight of or ignored. The truss applied at that time caused sufficient traumatism to produce adhesions which imprisoned the testicle in the upward reflection of the sac, and the enterocele, or hernia proper, recurred in the lower peritoneal pouch, possibly another case of pantaloon sac.

DISCUSSION

Dr. Duncan Eve, Nashville: The success of all operations for the relief of hernia depends on obliteration or removal of the sac, and the transplantation of the cord to the new bed or canal.

Dr. C. W. Allen, New Orleans: In a case of double inguinal hernia I completed the operation on the side where the sac was. I had transfixed the sac and proceeded to the other side; when I got to the sac there was a gush of blood. The blood came from the abdominal cavity. I knew I had not injured the deep epigastric artery on the other side, but something was wrong. I put the forceps on the side I was then operating on, went back, opened up the hernia on the other side and found that the ligature had slipped, and the hemorrhage was coming from the small vessel in the sac. We closed the sac and evacuated the blood in the cavity. That is the only time this has happened to me.

Dr. J. L. Crook, Jackson, Tenn.: The reason we do not operate more frequently for hernia is that we are perhaps negligent in pointing out to our patients the necessity of it. Men wear trusses for years when a simple operation with a very low mortality would make them practically perfect men physically.

Dr. Robert Caldwell, Nashville: It is not so much the removal of the sac *in toto* as it is the treatment of the exudate about the neck of the sac. Ochsner, of Chicago, was the first to advise simple treatment of the neck of the sac of a femoral hernia and he got results that were almost perfect. We are going to have recurrences whether we use the Bassini, the Ferguson, or the Macewen method, because we have to deal with different conditions. I do not see why we should transplant the cord instead of allowing it to stay in place, treating the neck of the sac properly, and supporting the internal ring, if necessary constricting that so as not to invite subsequent hernia. I do not see why in routine work we should still do the Bassini.

Dr. Willis C. Campbell, Memphis: In all cases at the New York Hospital for Ruptured and Crippled, a plaster spica is applied after the operation which immobilizes the parts absolutely and gives opportunity for quicker healing and leaves practically no dead spaces.

Dr. Charles A. Robertson, Nashville: Why are we not more frequently called on to operate on hernia? The reason for it lies in the fact that fitting trusses is largely in the hands of instrument dealers and druggists, who make false claims in regard to the permanent or curative value of the truss. It is a sad commentary on our profession that we have allowed these cases to get out of our hands and go primarily for treatment to men of this class, and I suggest that it is our duty to discourage patients from going to these men, and to urge on them the necessity of operation.

DR W D SUMPTER, Nashville The operation can be performed under local anesthesia with comparatively little pain If local anesthesia were resorted to more frequently more men would be operated on for the relief of this condition who fear a general anesthetic

DR PAUL DEWITT, Nashville There is no doubt that the operation for the radical cure of hernia can be performed just as completely under local anesthesia as under general anesthesia I have yet to find a patient who suffered any amount of pain during the operation

Operative Treatment of Fractures

DR C W ALLEN, New Orleans The view of operating on all fractures will never become universally adopted A more conservative middle ground seems the wiser, and to this group most conservative surgeons belong We learn from the study of the after condition of fractured limbs that a timely operation could have done much toward improving the functional usefulness of many of them A general anesthetic is demanded for the proper reduction of all fractures, except the simplest All fractures after reduction should be skiagraphed, and it is often found that what was thought to be a well reduced fracture, proves to be far from satisfactory In many cases reduction is possible, but cannot be maintained owing to the obliquity of the line of fracture When reduction is impossible operation should unhesitatingly be performed and one frequently finds on operating on such cases that the interposition of soft material would have made reduction impossible by any other than operative means The time for operation calls for some judgment In cases seen early, within the first twenty four hours, when there is not much injury to the soft parts, operation had best be done at once When there is extensive injury to the soft parts, or when several days have elapsed before first seeing the patient, delay should be advised until the local inflammation subsides, sometimes about the second week, when there will be less danger of infection I think far too many limbs are needlessly cut off With a little hard work and some ingenuity on the part of the surgeon many badly mangled limbs can be saved So long as the blood supply is sufficient to keep alive the peripheral parts there is a chance It is better that such patients spend six months in a hospital and walk out sound and able to make a living than to be discharged after three weeks with the loss of a limb, and spend the rest of their lives as hopeless cripples or helpless charges on the community

DISCUSSION

DR W P MCADORY, Birmingham A number of years ago I had a negro patient who was shot through the middle of the femur I kept the limb in extension for five weeks, at the end of which time I found that I had an ununited fracture I cut down on the seat of the fracture and found the bullet interposed between the ends of the bone I resected both ends of the bone, wired the fragments, and succeeded in giving this man a useful limb

DR H A ELKOURIE, Birmingham I would rather cut down on the bone and fix or wire the fragments together than trust to hypothesis and get bad results

DR A G PAYNE, Greenville, Miss In compound fractures it is best to operate, open up thoroughly, use phenol, tincture of iodin, peroxid of hydrogen, or bichlorid of mercury, but be sure the wound is thoroughly clean Any mechanical device you may see fit to use to hold the fragments in position will work if you are clean about it

DR MICHAEL HOKE, Atlanta As an orthopedic surgeon I am called on to correct many deformities the result of badly united fractures There are many things in the books on fractures that are absolutely wrong For instance, if the practitioner puts up a fractured elbow joint in the position of flexion and does not incorporate the shoulder, he cannot control the upper fragment, the shaft of the humerus Similarly, if he has a fracture of the forearm he cannot control the fragment unless he locks that up by putting it straight

DR JOHN SMITH, New Orleans I must differ with those who want to operate in every case I think that would be a mistake I have under treatment a young girl who sustained a fracture of the humerus about an inch and a half above the elbow joint, supracondyloid in which case the upper fragment goes backward and the lower fragment is tilted forward These fractures were put up in flexion, with a weight on the elbow joint, after the suggestion of Lovett and Stimson After repeated examinations with the Roentgen ray apposition was found very good, and after eleven days the splint was taken off, the arm massaged a little, and a light plaster splint reapplied The girl will not only have a good functional result but a good cosmetic result

DR ROBERT CALDWELL, Nashville I believe that operative treatment of compound fractures should be the rule and nonoperative treatment the exception Of course, much will depend on the character of the fracture If we have a transverse fracture, we know that if we reduce it, it is comparatively easy to maintain it in position and we secure good results by non operative treatment, but if we have an oblique fracture, or a spiral fracture, although we have secured reduction, it is difficult to maintain it, consequently knowing the comparative rarity of a true transverse fracture, we would say that operative treatment should be the rule and non operative treatment the exception

DR DUNCAN EVE, Nashville Until recently we were very well satisfied with firm union We did not think much about the question of permanent results, but since our ideal has been raised by the Roentgen ray we not only insist on a good functional result, but also on a cosmetic one While I am not opposed to the operative plan of treatment of fractures, I am not modern enough yet to suggest that all closed fractures should be treated by the open method In compound fractures this method is all right because you have an open wound Also for those fractures which cannot be reduced, or which when reduced, will not remain in coaptation, but the time has not arrived when surgeons will generally accept the open method as an every day plan for the treatment of closed fractures

DR E DENEGRE MARTIN, New Orleans The first and most important thing is to know the character of the fracture, and above all the anatomic structures involved If you have a simple transverse fracture, you are a poor surgeon if you cannot reduce it and hold it in position If you have an oblique fracture due to torsion, you are dealing with contraction of certain muscles and you will have trouble in holding the fragments in apposition and you must overcome the action of the muscles if you would get good results

End Results of Surgical Operations on Nervous Women

DR S T RUCKER, Memphis Nervous women, as a rule, do not make good subjects for surgical operations An operation should not be undertaken unless there is a definite, unmistakable pathologic lesion, and it is the chief cause of the nervous symptoms A correct estimate of the end results of surgical procedures cannot be made unless the surgeon keeps in touch with his patients for months after they return home. In clearing up diagnoses in obscure conditions, every surgeon should seek the aid of a competent internist, neurologist, and pathologist When a patient presents herself, she seeks relief from suffering She is not especially anxious to be cut, but to be cured, and the surgeon should always ask himself the question If this were my wife, or my daughter, would I advise an operation?

DISCUSSION

DR A A HEROLD, Shreveport I recall distinctly the case of a woman who was operated on four times, first, for a retro-displacement of the uterus, second, for the removal of one or both ovaries, third, for the removal of the appendix, fourth, for the removal of a kidney Finally, she was transferred to the neurologic department, and what became of her after that I do not know

DR GEORGE R LIVERMORE, Memphis A man came to me for diagnosis and possible operation for kidney stone He gave obscure nervous symptoms, with violent pain in the right side The diagnosis of appendicitis had been previously made by another physician He was operated on and his appendix removed, but the pain was just as severe as before Then a diagnosis of gall stones was made by a surgeon in Cincinnati, who operated for that condition. No gall-stones were found. The gall bladder was drained, and the pain was just as severe after this operation as before. I thought his condition was more hysterical or neurasthenic than otherwise. Urinalysis was negative. He had never passed any calculi. Roentgen-ray examination showed no stone in the kidney, nor shadow anywhere, and so I refused to operate, and advised him to consult a neurologist.

DR. J. A. CRISLER, Memphis: I recall the case of a physician who had all the evidences of neurasthenia, including genuine hysteria, and who had the notion that he had a bad gall bladder and a bad appendix. I refused to operate on him. He went to every surgeon in Memphis. He then went out of town to consult another surgeon, who removed his appendix and drained his gall bladder, and he has since been perfectly well. We might cite these cases one after another and prove, on the other hand, that surgery was indicated.

Surgical Treatment of Hepatic Cirrhosis

DR. ARTHUR A. HEROLD, Shreveport: I believe that all well marked cases of atrophic cirrhosis of the liver should be advised to submit to surgical procedure. I do not consider the results obtained, on the whole, brilliant, but I do not believe that a failure to benefit one of these cases by operation will injure the reputation of either the surgeon or of surgery.

Why Ligate the Sac in Hernia?

DR. H. A. ELKOURIE, Birmingham: I have done within the last six years twenty-two herniotomies without removing the sac. There has not been a single recurrence.

Coxa Vara

DR. WILLIS C. CAMPBELL, Memphis: The diagnosis is not difficult. As a rule no medicinal measures are indicated, but thyroid extract deserves a trial. In patients of moderate size a simple stilting abduction brace should be used until the bone is firm, when an osteotomy can be done below the lesser trochanter by any of the various methods, and the extremity held in abduction and internal rotation by a plaster spica, including the foot below and extending to the nipple or axilla above. I do not believe that a brace would be satisfactory in a fat subject such as my patient is, but when further reduced we may be able to use any desirable method. At present the patient is in a plaster spica extending to the nipple line, and the extremity held in as much abduction as possible. The condition has probably been present for one year, and at the expiration of two more years a corrective osteotomy can be done with excellent functional result if there is no further change visible by the Roentgen ray; otherwise we must wait until the process is stationary. In the meantime, I shall apply successive plaster spicas with forcible abduction and internal rotation, which may restore the angle sufficiently to give perfect function.

Purgatives with Pain in the Abdomen

DR. C. N. COWDEN, Nashville, Tenn.: There is no place for the administration of a purgative with pain in the abdomen unattended by a diarrhea.

The patient's danger lies not in the fact that the bowels do not move, but in the condition that produced the pain and obstruction, and the administration of purgatives of any kind under these circumstances is not only irrational, but is productive of the greatest harm to the patient. He does not get well because you force his bowels to move, but in spite of the effect of your drastic measure. Why not be rational in the treatment of these cases and meet the indications with remedies or measures that are indicated and not by the indiscriminate use of purgatives?

Human and Bovine Bacilli from Isolated Cases of Cervical Adenitis

DR. WILLIAM LITTERER, Nashville: Eleven consecutive cases of primary tuberculous cervical adenitis were studied, which resulted in the isolation of five cultures of *Bacillus tuberculosis* of the *typus humanus*, and six cultures of the *typus bovinus*. The classification of the types was made on the basis of four tests: First, the morphologic characters of the cultures; second, the dysgenetic or eugenetic characters of the cultures; third, the relative virulence toward rabbits, and, fourth, the reaction curve in 5 per cent. glycerin bouillon. This latter test serves admirably to distinguish between the two types, provided careful control tests be adhered to rigidly. I have found the differences in the growth of the two types, dysgenic and eugenic, on Dorset's egg medium to be very valuable in differentiating one type from the other. Rabbit virulence has probably been more uniformly satisfactory than any other of the tests in determining the differences between the two types of bacilli. In gathering up the clinical data of the eleven cases, I was unable to discern a single feature of distinction between those persons who harbor the human type of bacillus, and of those who were infected with the bovine type. The only striking difference observed was the result procured from the administration of tuberculin. In order that uniformly satisfactory results be obtained from the therapeutic administration of this agent, it is imperative that the nature of the type of infection be determined, so that a corresponding strain of tuberculin be employed.

The Gamete Carriers

DR. GRAHAM E. HENSON, Crescent City, Fla.: Until such a time as a campaign of enforced screening of all homes and public meeting places has been generally effected, it is imperative that in addition to the proper treatment of patients showing acute clinical manifestations of malaria, some means be devised to corral all chronic gamete carriers that either have frequent recurrences or possibly only after long periods of time, and that they be kept under treatment long enough to destroy all parasites they may be harboring.

Carbonic Acid Baths in the Treatment of Heart Diseases

DR. J. H. HONAN, Bad Nauheim, Germany: Carbonic acid baths have been used in cardiac diseases for over fifty years, and in all this time there has ever remained the question of their physiologic action. In all of my cases, with a pulse above normal, I have observed a slowing, and in but one case an increase. This was a very nervous man with a pulse of 60 and a subnormal temperature of 36.5 C., and blood-pressure of 140. In this patient I observed an increase of eight beats after an immersion of six minutes. In this action the baths resemble very much the digitalis group. If the high pressure is due to a poisonous irritation in the blood stream, the carbonic acid baths by their action of increased elimination, soon rid the blood of the toxic elements. In the blood tests which I have made there has in a large percentage been found an increase in the hemoglobin, and a better developed red blood corpuscle. The pulse is a good indicator to guide in the treatment and the duration of the baths. The results of my clinical studies convince me that carbonic acid baths in most cases reduce high blood pressure, raise low blood pressure, increase the pulse volume, increase elimination, increase pulse amplitude, increase heart energy, increase duration of temperature, reduce peripheral resistance, reduce dilatations, and relieve nervous irritability.

Infant Feeding

DR. MARGARET O. DAVIS, Nashville, brought out some points regarding the differences in human and cows' milk in infant feeding, the care of feeding utensils, etc. She emphasized the necessity of pure milk, and its preference to the use of drugs in some cases. The predisposition to disease of poorly fed children was touched on. She emphasized the need of certified milk in cities.

Cardiorenal Treatment

DR. J. B. GUTHRIE, New Orleans, spoke of the use of digitalis in heart diseases. He withholds a salty diet in cases of dropsy, which assists the patient in enduring the thirst, and makes easier work for the heart. Measure of the urine is the gauge of treatment, and rest, dry salt-free diet and purgation give as striking a change as we see with the addition of digitalis He recommends purgatives of strong salines or jalap in dropsy cases In acute dilatation he recommends venesection, as well as the use of opiates to insure rest He emphasizes the necessity of treating the heart muscle, even when the kidney or vessels are first affected, that is, to lighten the labor of the heart muscle by depleting measures, purgatives, diuretics if the kidney is sound rest in bed, when possible, by use of opiates if there is distress, and by the reduction of drinking fluids Digitalis may be given to prolong the rest period of the heart beat

Double Perforation in Typhoid Fever

Dr E M Folkes, Biloxi, Miss, reported two cases of perforation following typhoid fever One patient died eleven days after a successful operation for the closure of the perforation The diagnosis in this case was made early, and operation performed promptly

The names of the new officers elected were given in The Journal Nov 19, 1910, p 1819

TRI-STATE MEDICAL ASSOCIATION OF MISSISSIPPI, ARKANSAS AND TENNESSEE

Twenty Seventh Annual Meeting, held at Memphis, Tenn, Nov 15 17, 1910

The President, Dr J S Rawlins, Danceyville, Tenn, in the Chair

Officers Elected

The following officers were elected for the ensuing year President, Dr J W Barksdale, Winona, Mississippi, vice presidents, Dr John Darrington, Yazoo City, Miss, Dr Robert P Nall, Armorel, Ark, Dr Arthur G Hudson, Rein, Tenn, secretary, Dr Eugene Rosamond, Memphis (reelected), treasurer, Dr J A Vaughan, Memphis (reelected)

Memphis was selected as the place for holding the meeting in 1911

Injection Treatment of Infected Joints

Dr M G Thompson, Hot Springs, Ark A boy, 19 years of age, had had gonorrheal arthritis which resulted in ankylosis of the right knee of eleven months' duration Under local anesthesia a needle was thrust deep enough to enter the capsule No synovial fluid escaped, but an injection of liquor formaldehydi in glycerin was made The next day the knee was more painful The patient had some fever and was very much depressed mentally, but he was assured that in a day or two he would have a general anesthetic and the breaking up of the adhesions On the fourth day this was done, and after breaking up the adhesions and flexing the knee, the needle was thrust into it at the same point and at the same depth as at first, and the synovial fluid ran out freely The injection of the formaldehyd glycerin fluid was then made and the knee flexed several times This flexion relieved the pain very much In two weeks he could walk, and the knee had returned almost to its normal size

DISCUSSION

Dr Bernard Asman, Hot Springs, Ark I have treated twelve or fifteen cases by this method and satisfactory results have been obtained in all In some the relief was more prompt and more complete than in others but in none were there any untoward results observed An important point in regard to the formaldehyd in glycerin solution is that it must always be made up at least twenty four to forty eight hours before the time of using

Dr John L Jelks, Memphis Ten years ago I maintained that infections by the staphylococcus and by the tubercle bacillus could be controlled with formaldehyd solution I also pointed out that formaldehyd solution would destroy the gonococcic infection of the urethra within two weeks

The After-Care of Anterior Poliomyelitis

Dr Willis C Campbell Memphis, reported four cases of the disease, and in recapitulation said: The spine should be immobilized during the period of muscular excitability, as we would any acutely inflamed joint with muscular spasm The anatomic relation of the joint surfaces should be maintained to prevent deformities from muscular contraction Deformities, when present, should be corrected by surgical procedures Massage and electricity are dangerous measures in inexperienced hands Light braces which should maintain the parts in correct position Operative measures give brilliant results in well selected cases Rarely can a perfect functional result be obtained, but all can be benefited materially

DISCUSSION

Dr G G Buford, Memphis Anterior poliomyelitis is not confined to infants alone It has been my experience to find nearly as many cases of this disease in adults as in infants The etiologic factor in the production of anterior poliomyelitis is an inflammatory condition in the anterior horns of the spinal cord There are three classes of inflammatory conditions An exudate is present in all In one class the exudate is absorbed and those patients get well In others it is not absorbed In still other cases the cells are involved, and a paretic condition follows In the adult cases an infection results from anything which will produce a toxin

Dr W T Pride, Memphis Anterior poliomyelitis is an infection, and as typhoid selects the intestinal glands, so the infective organism of anterior poliomyelitis selects the ganglion cells especially the giant cells, of the anterior horns of the spinal cord There are those who believe that heat has a great deal to do with the development of the disease Operation in a great many cases is satisfactory By transplantation of the tendons a useless arm or useless leg has been made partially useful Various orthopedic apparatus are useful When the case is diagnosed early and paralysis has occurred, the general practitioner should send the patient to an orthopedic surgeon

Dr W L Wadlington, Memphis I have had under my observation for the last two months a woman three months advanced in pregnancy The trouble began with fever and an acute toxemia, resulting in complete paralysis of the body There has been a partial recovery from the paralysis in the upper limbs, but not in the lower I am waiting with much interest for delivery in this case to see what the outcome will be

Dr W C Campbell, Memphis In New York they have done a great deal by immobilizing the spine in the acute stage and in keeping the patients quiet The deformities which result from anterior poliomyelitis should be corrected as soon as possible We see comparatively few deformities from this disease in the clinics of America as compared with those seen in London and Vienna

Anxiety Neuroses

Dr S T Rucker, Memphis Anxiety and worry are distressing symptoms in many of the so called neuroses, but are most common and constant in neurasthenia, hysteria, melancholia, and psychasthenia In many cases of hysteria, anxiety and worry are annoying symptoms The patient may constantly refer to some sensation which she interprets as an incurable malady One patient, whose appetite and digestion were good, complained incessantly that she had an incurable stomach trouble Another patient had a morbid fear of dying In melancholia and psychasthenia anxiety takes the form of a fixed obsession or hallucination, and its manifestation is often distressing to witness One of my patients would walk the floor crying and displaying great agitation over the belief that she had brought financial ruin to her family When anxiety and worry are symptoms in the illness of patients, there is no drug or remedy that will take the place of psychotherapy The physician who has the ability to put his patient in a cheerful frame of mind and fix the belief that he will recover has at his command a most effective therapeutic procedure

Bacterial Vaccines, a Factor in Therapeutics

Dr William Litterer, Nashville In no instance have I failed to observe improvement in any mixed tuberculous affection I would encourage the use of vaccines as an adjunct to medical and surgical procedures in certain types of infections which up until now have stubbornly resisted all curative measures. In every instance a sinus or fistula of long standing, whether tuberculous or not should be given the benefit of vaccine therapy. Autogenous bacterines should be used when possible. Stock vaccines are uncertain. In every case of mixed tuberculosis (pulmonary or otherwise) beneficial results have been obtained by employing the autogenous vaccines and tuberculin.

Surgical Treatment of Goiter

Dr. W. T. Black, Memphis: Thyroidectomy is the usual procedure in hyperthyroidism but in cases with symptoms of beginning hyperthyroidism or where the symptoms are not severe enough to warrant a thyroidectomy, ligation will often cure the patient. It is also indicated in every acute case, and in chronic cases which have resisted other forms of treatment, and in which there are secondary changes in other organs. Ligation may be performed either under general or local anesthesia. The ligation of the upper poles has met with satisfactory results in a limited number of cases. I believe if we study the mental as well as the general condition of our patients, and operate oftener by ligation as a preliminary measure, we will reduce to a minimum the risk these patients run.

DISCUSSION

Dr. B. F. Turner, Memphis: Surgery of the thyroid gland involves one other branch of medicine which heretofore has been frequently overlooked. The effect of hyperthyroidism as a cause of dementia has not received the attention that it deserves. Alienists are beginning to recognize that here and there is a patient who is a proper subject for the surgical infirmary rather than for the detention house for the insane. The operations that have been performed on this class of cases have given satisfactory results. I wish to emphasize the necessity of consulting a surgeon with reference to the possible existence of hyperthyroidism and its correction by operation in those cases in which some form of mental derangement would seem to suggest the advisability of incarcerating a patient in an insane asylum.

(To be continued)

PHILADELPHIA COUNTY MEDICAL SOCIETY

Meeting Held Oct. 12, 1910

The President, Dr. Henry Leffmann, in the Chair

SYMPOSIUM ON FOOD IN HEALTH AND DISEASE

Dr. John Marshall spoke on the "Chemistry of Foodstuffs."

Food in Health

Dr. W. E. Robertson: Food in health is a subject that receives too little attention from the physician. Dietetic errors in the direction of quality and quantity are probably responsible directly for much of the minor ill health with which the doctor has to deal, and indirectly, by lowering the body resistance, inviting the development of acute infections, or that which is more serious, metabolic disease. Foods may be discussed very broadly as nitrogenous and non-nitrogenous, and according to their nutritive constituents as proteins, carbohydrates and fats. Proteins we regard as tissue builders and repairers of waste tissue. Carbohydrates and fats produce energy and both, but especially the carbohydrates, are regarded as protein sparers. I consider the total amount of food requisite to furnish about 3,500 calories per day, the amount generally agreed on as being essential for the average worker. I would commend especially a nut diet as being both economical and furnishing a high food value.

Food in Disease

Dr. M. Howard Fussell, Philadelphia: I believe that in the vast majority of cases which a physician is called to attend, nursing, proper food, and fresh air are of much more importance than drugs. The food prescribed in disease must be of such a character that it will not embarrass the already weakened powers of digestion. On the other hand it is just as important that the food contains sufficient calories for the maintenance of nourishment. The chief value of beef tea or other broth without albuminous matter, is in the mental effect which such foods create and the water and salts which they contain. Water should be administered regularly to patients who are ill enough not to ask for it. When practicable the caloric value of the food we administer to our patients should equal that of a diet of health, an average of 2,500 calories daily being about the necessary amount. With patients suffering from typhoid I now add to the diet soft eggs, soft toast, cereals well cooked, very finely minced meats of various kinds.

DISCUSSION

Dr. James Tyson: The only condition under which food acids can be harmful to gouty patients is their excessive use so as to overwhelm the stomach contents with acidity. Regarding the use of red and white meats, it is much worse for the patient to take half a pound of chicken than a quarter of a pound of beef. In acute Bright's disease or in the complications due to uremic poisoning, there is nothing comparable to a milk diet. In typhoid fever I am in the habit of saying that a suitable diet is one of liquid of which milk is the principal portion. Farinaceous and soft foods are suitable for these cases. I do not permit eggs to be given until the patient is convalescing. Ice cream is an admirable food in typhoid fever. Individual peculiarities demand changes in diet.

Dr. M. B. Hartzell: We know too little about the chemistry of digestion and the metabolism of food to formulate any definite rules as to the treatment of our patients by diet. We can advise our patients intelligently only by having them under observation over a considerable period of time. Generally speaking, I should favor a fairly liberal diet, with fruit included.

Dr. H. B. Allyn: What might be called the time habit is important in diet. For example, fruit in the morning is much less apt to disagree with digestion than when taken at night. Eating late at night is apt to cause difficulty because the whole digestive apparatus is less energetic than at an earlier hour. If we could manage to control constipation by dieting measures it would be much better for the patient than the use of pills.

Dr. Richard C. Norris: From the obstetric standpoint, I can say nothing that is not already known. I know of no one single factor that adds so much to the danger of the pregnant woman as the fault of over eating. I think it a good practical working rule to suggest to such women the omission of the mid-day meal and the substitution of milk and crackers. Of primary importance from the standpoint of diet is the toxemia of pregnancy. I have been much impressed with the importance of a milk diet in these cases. By some it is regarded as the mainstay in the prophylactic treatment of eclampsia.

Dr. Kate W. Baldwin: I recall the case of a pregnant woman who passed the full term of her pregnancy on rectal feeding and was delivered of a well developed 8 pound child.

CITY OF WASHINGTON BRANCH OF THE AMERICAN PHARMACEUTICAL ASSOCIATION

Regular Meeting, held Nov. 11, 1910

The members of the Association of Official Agricultural Chemists were guests at this meeting and the subject under discussion was

The Pharmacopeial Convention of 1910 and the Prospective Pharmacopeia of the United States

Dr. H. W. Wiley, president of the United States Pharmacopeial Convention, presented a communication in the course of which he outlined his opinions regarding the Pharmacopeia and the methods to be followed in revising it. Among other things Dr. Wiley said:

"One of the most important points, it appears to me, is to see to it that the two great interests represented in the revision of the Pharmacopeia work is complete harmony in the revision which is now taking place. I refer on the one hand to the profession of pharmacy and on the other to the profession of medicine. Practically all of the members of the committee represented one or the other of these great professions. I may say further that the two great professions are equally interested in the matter, but from different points of view. Complete harmony will be secured if the members of the two professions on the committee seek to restrict themselves as nearly as possible to their own peculiar fields of investigation. * * * The pharmacist and the physician, therefore must join hands and work side by side to secure what is best in this new revision. I may say broadly that the line of cleavage is distinct in respect of the attitude of these two professions. The physician is the one undoubtedly who should study the therapeutic effects of drugs. His training has fitted him for this function and he has been taught, usually by large experience, to note with scientific accuracy the effects which different drugs produce on the human organism, especially in a state of disease. While the physician is not a pharmacologist necessarily in that he is not called on to determine the effects of drugs on perfectly healthy animals, he must be a pharmacologist in that other sense of studying the effects of drugs on the diseased organism. In other words, he is more of a practical than a theoretical pharmacologist. The pharmacist, too, is interested in pharmacology and it is perfectly proper that he should also study, for his own benefit and for the benefit of his profession, the action of drugs, but not with a view of administering them to a patient.

ADMISSION OF USELESS DRUGS

"It may be said that the Pharmacopeia is no place to speak of the therapeutic effects of drugs, and this may be true. Let us grant that this is the case, nevertheless a drug only finds a place in the Pharmacopeia because of its therapeutic effects, which must be well understood, although they may not be set forth in the Pharmacopeia. In other words, it seems to me that the medical members of the Committee on Revision would have a right to object to the introduction into the Pharmacopeia of drugs the therapeutic effect of which is unknown or *nil*, and to require that the Pharmacopeia should include only those drugs which really have a therapeutic value. I know it is difficult to properly discuss so delicate a question when the interests of two professions are at stake, but I will ask if there could be any just reason for including in the Pharmacopeia a remedy the therapeutic value of which is zero, or at least of an uncertain quantity? I can see no just ground for admitting such a drug to standardization in the Pharmacopeia.

"It may be that the pharmacist would have a greater business if he sold large quantities of drugs which produce no therapeutic effect, and it may also be true that physicians would have better success at times if they gave more placebos, producing no effect, but it seems to me that is not the question here. Drugs are supposed to be useful even if their abuse may be dangerous, and unless they have some recognized utility they can not with any justice find a place in the Pharmacopeia. That it was the purpose of the Convention to exercise a wise discrimination in respect of the new matter which should go into the Pharmacopeia and the old matter that should go out is evident. In fact it will be remembered that the Convention took at first a somewhat radical stand in regard to this matter, which was afterwards modified on the distinct understanding that the Executive Committee on Revision should act as a strict censor in regard to these matters.

"The subject was also taken in consideration in the section on pharmacology of the American Medical Association, which reached very positive conclusions that the Pharmacopeia should be freed from all useless preparations, and even from those of doubtful efficacy. Equally severe scrutiny of new matter is also to be recommended. New remedies which have not been established by long experimental use are to be looked on with suspicion, such as buttermilk as a prophylactic against premature death, and many other substances which are fads and fashions rather than remedies founded on facts. At the same time it must be remembered that while one physician might deem a drug of no therapeutic effect, there might be a thousand who would think it valuable, and in such case the wish of the majority should be followed.

THERAPEUTIC NIHILISM

"There is a growing disposition, and I may say perhaps happily so, to discredit the therapeutic value of drugs. Advancing knowledge has convinced thinking people that drugs as a rule do not cure, in fact, under the Food and Drugs Act prosecutions have been instituted for false claims respecting the virtues of drugs because they are held up as a cure for certain diseases. It seems to me that there is a just prejudice forming, not only among the laity, but also in professional circles, against elaborately compounded articles consisting of a great many different substances. These articles seem to be prepared with an idea that there may be something in the compound which will hit the mark. It might be very properly called 'shot gun' pharmacy and 'shot gun' therapeutics. It is perhaps very natural for a physician who is uncertain about a case to fire such broadsides in the hope that some of the preparations may become effective. The pharmacist, of course, has nothing to do but to fill the prescription which is sent to him. This prejudice against drugs has doubtless been greatly augmented by the cure-all nostrums which have been so widely advertised, and I may say that in spite of all the work that has been done the cure-all fakir still has a firm hold on the American public. I have often been surprised, and even very recently, by the unqualified confidence reposed in a patent nostrum by intelligent people.

"There is a constant question of the efficacy of drugs and certain schools of therapy have sprung up offering to cure diseases by diet, by exercises, by contortions, by electricity or by all combined, preaching the dangers of the drug habit and its lack of efficiency. All of these things only accentuate what every physician knows, namely, that drugs are no certain cures, and even frequently no certain aids. This condition of disbelief and unrest should not be allowed to go too far because we know that drugs are efficient and useful. It is important, therefore, that in the Pharmacopeia such safeguards should be thrown around the remedies therein described and such conservatism practiced in speaking of their therapeutic effects as to inspire a greater degree of confidence in the minds of the public at large in the utility and efficiency of these remedies.

"This condition of scepticism in the public has been described by one author as 'therapeutic nihilism' and the growth of this distrust in connection with medicinal reagents is clearly pointed out. Much will be done to stem the tide of this destructive tendency by the wisdom and care with which the next United States Pharmacopeia is compiled. There is resting on the Pharmacopeial Convention and its general and executive committees of revision a task of great magnitude attended with obligations of the most serious character."

PROF. JOSEPH P. REMINGTON, chairman of the Committee of Revision, outlined the nature and amount of work that had been accomplished during the summer months. He expressed the belief that the real sentiment of both physicians and pharmacists was neither in favor of a skeleton pharmacopeia nor of a padded pharmacopeia, but of what he was pleased to designate as a sane pharmacopeia.

Prof. Remington also pointed out that for many years the Pharmacopeia was a closed book to the medical profession because its members had been led away from it by the detail man of the manufacturer and proprietary medicine maker. The resulting decay of therapeutics has brought about a state of confusion and a tendency to therapeutic nihilism that he considers to be most unfortunate. He holds that physicians do not know a sufficient number of U. S. P. preparations and do not appreciate the fact that their fellow practitioners in different parts of the country, and in different cities, use totally different medicines for which the Pharmacopeia of the United States should furnish standards.

DISCUSSION

Prof. I. V S Stanislaus, Philadelphia, asserted that the paper by Dr Wiley had been to him a revelation He had been particularly impressed by the reference to needless duplication of drugs having similar properties, and willingly endorsed the proposition to delete useless duplications from the Pharmacopeia He pointed out that the content of previous pharmacopeias represented the selection and dictates of the few and not of the many and hoped that greater care would be exercised regarding admissions and deletions

Dr Murray Galt Motter secretary of the Pharmacopeial Convention, pointed out more particularly that the work and the function of the executive committee as outlined by Dr Wiley, was in accordance with the intent and purpose of the board of trustees of the former convention He also pointed out that the professional representation on the General Committee of Revision was not alone interesting, but rather significant Of the total number thirty four (indeed thirty five when a vacancy was filled) were nominees of the pharmaceutical caucus and but sixteen were nominees of the medical caucus Of the latter it is also interesting to note that only two reached the executive committee

In connection with the scope of the Pharmacopeia he pointed out that the Pharmacopeial Convention by a vote of ninety five to forty seven emphatically recorded its conviction that substances 'whose value and use have not been established" should not be included And then, on the plea that it was unnecessary to hamper the committee elected for the purpose of carefully selecting the list of substances, the convention was induced to strike out, by a vote of one hundred and twenty three to forty this 'ambiguous and dangerous provision," thus leaving the final decision regarding scope with the members of the General Committee of Revision

With reference to the business of the Pharmacopeial Convention he asserted that it had been pointed out by several observers that 'the financial statement made to the Convention was in no wise satisfactory, explicit, or in justice to the intelligence of the body to which it was delivered" In commenting on 'the enormous sales of the book amounting to nearly 40 000 copies the first year" he pointed out that as a matter of fact the sales of the Pharmacopeia did not reach 40 000 until the middle of 1908

In concluding he expressed the belief that if those who are to effect the work of revision do not clearly realize their responsibility to the convention and to the several professions represented, and produce a book of standards, indeed, but of standards for substances of established value and use, the next Pharmacopeia, instead of being a force, will be a farce

Dr Reid Hunt, chairman of the American Medical Association Committee on the Pharmacopeia, pointed out that regarding the scope of the book there were two diametrically opposed views, both of which deserve consideration The manufacturer and the pharmacist desire to have a book of standards that will include all of the substances that are, have been or may be used as medicine, while the medical practitioner desires to have a book of standards for the approved therapeutic agents only so that the book may be used as a basis for instruction in medical schools and as a guide to the physician who is willing to adopt and use recognized standard remedies It must be evident that these two objects are so totally different that it would be practically impossible to agree on a compromise, and any attempt to do so would be considered a straddle that could be acceptable to but few

He heartily endorsed the stand taken by Dr Wiley regarding the scope of the book and expressed the belief that physicians and pharmacists should not be expected to furnish standards for Custom House officials and 'patent medicine" manufacturers As chairman of the Committee on the Pharmacopeia of the American Medical Association he had been able to get into communication with thousands of medical practitioners in various parts of the United States, all of whom were willing to use the best medicines that were available and desirous of obtaining authentic information regarding the probable efficiency of drugs.

Dr Hunt outlined the methods that had been employed by his committee to secure the cooperation of the several sections of the American Medical Association and referred more especially to the correspondence that had been had with medical men in active practice who were also teachers of materia medica and therapeutics in medical schools and colleges, and asserted that despite the fact that the evidence thus secured had been submitted through the Pharmacopeial Convention to the Committee on Revision, many of the members appeared to be willing to ignore the wishes of physicians and that the indications were that the scope of the forthcoming Pharmacopeia would again represent the views of but a limited number of individuals

As an indication of the opinions held by the better informed medical men he quoted Dr. Abraham Jacobi, the Nestor of American physicians, who in discussing the content of the present Pharmacopeia deplored the fact that the makers of the Pharmacopeia were not willing to restrict the book to the best remedies only

Dr W M Barton seconded the remarks made by Dr. Hunt and asserted that he had also come to the conclusion that there are two diametrically opposed opinions regarding the scope of the Pharmacopeia and was satisfied that the book cannot, as it now stands, be accepted by medical men as a guide He suggested the possibility of limiting the medical recognition of drugs by introducing a fair statement of the physiologic action of the substance with each description

10 Reveries of a Young Practitioner F McK Bell, Ottawa, Ont, Canada

3 **Extramedullary Glioma**—The course of the disease in this case was that of a slowly progressive segmental lesion, in the earlier stage of development unilateral, giving the clinical aspect of the Brown Séquard symptom complex The characteristic pain, distinctly localized, due to nerve root irritation, was prominent from the beginning and at no time did the diagnosis of spinal tumor seem doubtful The patient was seen very early by Dr George Dock At that time the only symptom was a pain sharply circumscribed in the one area supplied by the seventh thoracic nerve There were no other symptoms, and Dr Dock concluded that the cause was not due to any disturbance of the internal organs, and that it was a distinctly localized condition limited to the seventh thoracic nerve It was clearly shown by the attachment of the tumor that there could not have been at the beginning of the neuroglia proliferation any involvement of the corresponding segment Although originating very close to the spinal cord itself, the pain was referred from the nerve root The tumor was removed and the patient made a complete recovery

9 **Epilepsy**—Levin holds that vascular phenomena precisely similar to those occurring in asthma, or angioneurotic edema, occur in the brain with each epileptic seizure The violent symptoms occurring during an epileptic fit are explained by the sudden increase in the intracranial pressure entailed by this exudation within the rigid, unyielding walls

of the skull As soon as the pressure within the cranium has readjusted itself the symptoms will pass off To support his contention for the inclusion of epilepsy within the class of angioneurotic affections various facts are brought forth In common with the other manifestations of the exudative diathesis, it has a constitutional irritability of the nervous system as its principal etiologic factor. Just as attacks of bronchial asthma have been sometimes associated with urticaria, or angioneurotic edema of the hands or feet, or have been known to alternate with attacks of hay-fever, so attacks of epilepsy have been known to alternate with attacks of bronchial asthma—as stated by Salter Furthermore, the premonitory symptoms which usher in some attacks of asthma are essentially the same as the auræ of epilepsy Since, according to this theory, each epileptic seizure is associated with an increase of intracranial tension it has occurred to Levin that possibly a decompression operation would be of service in this disease By removing a portion of the unyielding skull and substituting instead an expansile diaphragm in the shape of the scalp it will allow of quicker adjustment of intracranial tension, and thus, perhaps, diminish the frequency or severity of epileptic seizures

37 *Cutaneous Tests with Corn Extracts in Pellagrins A D Hirschfelder Baltimore

29 **Complement Fixation Tests for Syphilis**—The authors have found that the pure lipoid" antigen (ether extract) has proved the more satisfactory It has given, with syphilis, the largest percentage of strongly positive reactions by all three methods The alcoholic extract antigen, when used with active serum has given the largest percentage of non-specific reactions Inactivation apparently destroys the power of a non specific serum to cause a positive reaction The Noguchi method using active serum, gives the most sensitive reaction in syphilis, the Wassermann and the Noguchi "inactive" methods stand in the order named One of the most important factors in securing reliable results, when active serum is employed, is the performance of the reaction within twenty four hours after the serum is obtained

31 **Peculiar Red Corpuscles in Anemia**—In the case cited by Herrick, the condition was evidently chronic as revealed by the history of the past three years, with yaws and suppurating otitis as predecessors, yet with acute exacerbations The condition was not clearly explained on the basis of an organic lesion in any one organ There was cardiac enlargement albuminuria and cylindruria, general adenopathy, icterus, with a secondary anemia not remarkable for the great reduction in red corpuscles or hemoglobin, but strikingly atypical in the large number of nucleated red corpuscles of the normoblastic type and in the tendency of the erythrocytes to assume a slender sickle like shape The leukocytosis with a rather high eosinophil count was also to be noted Syphilis was suggested by many of the facts, such as adenopathy and the conditions of the heart and kidneys, it might explain the anemia, the arthritis and perhaps also the temperature, cough and attacks of pain resembling hepatic or gall bladder disease for, as is well known, visceral syphilis may furnish a most bizarre group of symptoms The Wassermann test was not in use at this time The scars said to have been due to yaws were like those left by syphilis The patient coming from the tropics, one thought of intestinal parasites such as uncinaria as a possible explanation of the anemia and the eosinophilia What were thought to be eggs were found on one occasion only, and after thymol there was temporary improvement The odd blood picture made one examine for possible toxic effects of the coal tar preparations, but neither from the history nor from the examination of the urine was there any evidence that such drugs were habitually taken The question of diagnosis, therefore, remains an open one unless reports of other similar cases with the same peculiar blood picture shall clear up this feature

32 **Elimination of Bacteria**—As a result of his experiments, Hess states that bacteria, using the *Bacillus prodigiosus* for the test, are excreted from the blood, not only by way of the liver through the bile, and the kidneys through the urine, but also, to a less extent, directly through the intestinal wall This was found to take place in one hour when one platinum loop of culture medium was inoculated In these experiments all other paths of access from the blood to the lumen of the intestines were absolutely closed off, including the path from above by way of the pylorus, and the entry by way of the pancreatic and the bile ducts It may be argued, says Hess that the severity of the operative procedure contributed to the result by rendering the intestinal wall less resistant, and by increasing its permeability It may be answered that this argument may be brought forward in the case of all experimental data In the experiments performed, the operations were carried out quickly and with as little handling of the intestines as possible Moreover, the question of complicating peritonitis or inflammatory reaction did not enter, as, apart from the careful asepsis observed, in almost all cases the animal was killed shortly after Although it is a well recognized fact that bacteria can pass with the lymph stream through the intact intestinal mucosa and then migrate from the lumen of the intestine to the blood, the reverse phenome

non, namely that they pass from the blood through the mucosa into the intestine, has, as far as Hess is aware, not previously been demonstrated

33 **Experimental Lung Anthracosis**—Purified talc was injected by Mace into the peritoneal cavity and after a certain time the animal was killed and the organ under observation completely burned in a platinum crucible The residue was treated on the water bath with hydrochloric acid In control experiments in which only a few milligrams of talc were added to the viscera, this substance was easily recovered and recognized Experiments made show that talc is not carried from the peritoneal cavity and mesenteric lymph nodes to the lungs during the maximum period of observation of these animals They do not prove that charcoal is not thus carried, but they add largely to the probability that it is not While it may be asserted, says Mace, that results obtained with talc cannot be applied to charcoal, on account of the great difference in density, size of particles, etc, it should be remembered that the silicates, under certain circumstances, form the basis of lung deposits, a natural lung silicosis being sometimes observed in potters and quarry workers Although the analogy between lung silicosis and lung anthracosis is certainly as great as the analogy between lung anthracosis and lung tuberculosis it cannot be held that these results apply conclusively to ingested tubercle bacilli They do, however, add important evidence against the theory that the origin of lung deposits is by way of the mesenteric lymph channels

34 **Adrenals and Pancreatic Activity**—The authors found that the removal of the suprarenal glands induces in dogs a flow of pancreatic juice This has been equaled in duration and activity only by the processes, natural or experimental which depend on activation by duodenal secretin Taken in connection with the inhibitory action of suprarenal and pituitary extracts on the pancreatic flow, this suggests a control over the pancreas, by the adrenals at least, in the absence of which the gland secretes more actively This activation of the pancreas may occur with a high systemic blood pressure, though it generally occurs when the systemic blood pressure is relatively low Hemorrhage may modify or prevent it There is some evidence to indicate that on the death of a dog from removal of the adrenals, there is present in the duodenum more prosecretin than exists in dogs otherwise operated on which have their adrenals intact, and which die after a comparable long period of etherization This preponderance may be a contributory factor in the production of a flow One of the factors which seems to make detection of prosecretin in human beings difficult is probably the lingering death of most of those from whom the intestinal extracts are made In clinical investigations of secretin comparisons should not be made between such preparations and those from freshly killed animals, unless this fact be borne in mind

36 **Resistance to Compression of Arterial Wall**—The object of this study was to determine whether the resistance to compression of the arterial wall introduces an error of any importance in the clinical measurement of systolic blood pressure by methods employing circular compression of the arm The material examined was as follows 1 Twelve common carotids from infants removed post mortem, of which ten gave results free from obvious error 2 Twenty three common carotids and four iliacs taken from adults removed post mortem of which twenty gave results free from obvious error 3 Six arteries taken from amputated limbs, of which four gave results free from obvious error 4 Thirty eight common carotids and four mesenterics from the ox, of which eleven gave results free from obvious experimental error 5 Six samples of rubber tubing of different caliber and lumen, one boiled artery. one esophagus, one segment of a small intestine Two other structures were examined An infant's esophagus was tested and found to compress absolutely at an increment of external pressure of only 1 mm Hg The intestine was also tested but fruitlessly, since its lax wall at once collapsed over the end of the outflow cannula The authors conclude that the arterial wall offers definite resistance to compression Other things being equal, small arteries with thin walls are more readily compressed than large arteries with thick walls In infancy and childhood the resistance of the arterial wall is a negligible factor in clinical blood pressure measurements. Arteries as large as the brachial may require only the pressure of a few millimeters of mercury for the obliteration of their lumen In adults with normal arteries and a normal range of blood pressure, the arterial wall is a practically negligible factor It probably never introduces an error greater than 10 mm Hg in clinical blood pressure measurements, a figure less than the spontaneous variations in pressure from minute to minute Atheroma, even of considerable degree, is without appreciable effect on the compressibility. Calcification of the arterial wall, when segments longer than 6 cm are examined, increases only moderately its resistance to compression The overpressure dependent on this factor in their experiments did not exceed 17 mm Hg In clinical blood pressure determinations, if a wide arm piece be used, and the return of the first fully developed pulse-wave be taken as the index, as recommended by von Recklinghausen, even advanced arterial thickening and calcification probably do not introduce an error of any importance The only factor determining the compressibility of an artery which seems capable of introducing an error of real importance in the clinical measurement of systolic blood pressure, is the state of contraction of its walls It is impossible from their experiments on surviving ox arteries to set definite numerical limits for this in man From these experiments, however, combined with the study of human arteries, after amputation and post mortem, the authors feel that a degree of hypertonic contraction of the brachial artery sufficient to cause an error of more than 30 mm Hg seems improbable, and of more than 60 mm incredible, during life The point of return of the pulse after obliteration, not of its disappearance during compression, should always be the criterion of systolic blood-pressure.

37 **Skin Tests with Corn Extracts in Pellagra.**—In these observations, cutaneous tests were made with substantially the same technic as that employed by v Pirquet in tuberculosis except that corn extracts were substituted for tuberculin in making the test The procedure was as follows: 20 gm of corn was extracted with 50 c c of ether, alcohol, 10 per cent sodium chlorid, or 0 2 per cent sodium hydroxid. The extract was filtered and 1/10 vol 5 per cent. phenol added to the clear filtrate so as to give it a content of 0 5 per cent phenol The ethereal extracts were allowed to evaporate at 46 degrees, until the odor of ether had disappeared The site chosen for the test was on the patient's wrist in an area which was subject to pellagrous pigmentation, thickening or desquamation, and, in most cases, was bare so as to be exposed to the action of light A drop of the extract to be tested was placed on the skin and a pin head area of epidermis beneath the drop was excoriated by the torsion of a v Pirquet stylet Into this excoriated area the extract was rubbed with a glass rod A series of epidermal punctures were made in this way in a line across the wrist, with another line of duplicate punctures above them. In each series there was a pair of controls in which only the pure sodium chlorid or sodium hydroxid solution or alcohol was placed on the skin Within half an hour after the puncture a small red or sometimes blanched areola and occasionally a small papule formed about the site of inoculation, but in only one case did this exceed 5 mm in size, and no differences could be noted between the areas about the punctures with corn extracts and the controls The reactions in sites which were nearest the midline of the forearm were often slightly more marked (areolæ about 1 mm larger than the rest), but these reactions were always quite as marked with the control fluids as with the extracts and hence were of little significance The reactions, which were regarded as negative in all cases, consisted of simple traumatic reactions, were watched for about half an hour and the sites of inoculation were again inspected three hours, twenty four hours, and forty eight hours later, as well as at frequent intervals between and after the expiration of these periods Extracts were made from samples of good corn, spoiled corn taken from the Arkansas Insane Asylum at the time of a pellagra outbreak, and a sample of spoiled corn containing *Aspergillus fumigatus* These reactions were all negative The results of

these tests, therefore, render it improbable that pellagra is due to or accompanied by a condition of hypersensitiveness of the individual to products derived from good or from spoiled corn

62 Determination of the Amid Nitrogen in Proteins W Denis, Boston

54 **Determination of Urinary Ammonia**—That sodium hydroxid may be advantageously substituted for sodium carbonate in determining the urinary ammonia nitrogen in normal urines is shown by Steel In order to ascertain whether sodium hydroxid, in the proportions employed in previous experiments and in the presence of a relatively large amount of sodium chlorid, would produce ammonia from amino radicals, weighed amounts (0.1 gram) of urea, uric acid, glycocoll, taurin, leucin, tyrosin, hippuric acid, guanin, allantoin, and mixed creatin and creatinin were added separately and collectively to 25 c c fractions of normal urines and, after aeration in the usual manner, the amounts of liberated ammonia nitrogen were compared with those from the original urines In no case was any increase observed These same substances were also added to 20 c c fractions of a standard solution of ammonium chlorid instead of urine and the ammonia content determined Here again no increase was obtained In Steel's opinion these results show conclusively that the ordinary organic constituents of urine are not decomposed by the stated proportions of sodium hydroxid, in the presence of a physical excess of sodium chlorid and under conditions favorable for the liberation of all the inorganic ammonia in normal urine As a final test of the efficiency of the modified method, the ammonia in fractions of a given sample of normal urine was separated by the Folin method and also by the modified method The results completely confirmed the conclusion already drawn to the effect that, in the case of urines containing crystals of triple phosphate the Folin method fails to give perfectly accurate results for ammonia content These results also still further emphasize the statement that sodium hydroxid in amounts varying from 0.5 to 1 gram plus about 15 grams of sodium chlorid may be substituted for the sodium carbonate as prescribed in the Folin method The modified method has therefore, a number of points in its favor, since many samples of pathologic urine contain crystalline triple phosphate

59. **Determination of Sulphur in Urine**—A modification of Benedict's method has been devised by Denis so as to prevent the too rapid evolution of the oxids of nitrogen The method is as follows To 25 c c urine contained in a porcelain evaporating dish of approximately 4½ inches in diameter, add by means of a pipette or burette 5 c c of a solution containing 25 grams of copper nitrate (crystals), 25 grams of sodium chlorid and 10 grams of ammonium nitrate Evaporate to dryness on the steam bath or with a very small flame, then heat gently with a small flame, gradually increasing the flow of gas until the dish is heated to redness, and continue to heat at the latter temperature for from ten to fifteen minutes Allow to cool and add from 10 to 20 c c of 10 per cent hydrochloric acid On gently warming for a few moments a clear solution is obtained Transfer to a 200 c c Erlenmeyer flask, make up to 100 or 150 c c with water, heat to boiling and add drop by drop 25 c c of a 10 per cent solution of barium chlorid Let stand one hour or more and filter on a Gooch crucible A blank must be run on 10 c c of the oxidizing solution as copper nitrate generally contains traces of sulphate, and the amount of sulphate thus found deducted in the final calculations By the use of the above described oxidizing mixture the spattering which is so prominent a feature in the Benedict method is entirely eliminated the only precaution necessary being the avoidance of too rapid heating at the beginning of the fusions If at this time the burner be turned up so rapidly that clouds of nitrous oxid gas are evolved the result will be low

60 **Estimation of Urea**—In the use of Benedict's method a sulphuric acid bath is required which must be kept at a temperature of from 162 to 165 F The technic recommended for the estimation of urea in urine is as follows 5 c c of urine are introduced into a rather wide test tube, and about 3 grams of potassium bisulphate, and from 1 to 2 grams of zinc sulphate are added (The quantities of these salts may be measured roughly An excess of the zinc salt is to be avoided, as too large a quantity tends to cause slight frothing during the final distillation) A bit of paraffin, and a little powdered pumice are then introduced into the tube (to prevent frothing and spattering) and the mixture boiled practically to dryness either over a free flame, or more conveniently, by floating the tube in a bath of sulphuric acid kept at about 130 F The tube is then placed in a sulphuric acid bath which is maintained at from 162 to 165 F (not lower), and left there for one hour During this heating the tube must be weighted (a large sized screw clamp is convenient), so that it will be immersed in the acid for at least three fourths of its length At the end of the hour the tube is removed from the bath, the acid washed off under the tap a little distilled water poured into the tube, and the contents washed (with the aid of heat) quantitatively into an 800 c c distillation flask (A small amount of black pigment finally adhering to the sides of the tube may be disregarded, as the ammonium compounds are readily soluble) The fluid in the distillation flask is diluted to about 400 c c, rendered alkaline through the addition of 15 or 20 c c of 10 per cent sodium hydroxid (or 25 c c of 15 per cent sodium carbonate), and distilled for forty minutes into an excess of standard acid The residual acid is then titrated, and the urea nitrogen calculated (after subtraction of the previously determined ammonia nitrogen) In dextrose containing urines this method may be employed in combination with the Morner Sjoqvist method

66 **Influence of Alcohol on Nitrogenous Metabolism**—A study of protein metabolism and utilization, and especially the partition of nitrogen in the urine, under the influence of alcohol was carried out on man and dogs under fixed and comparable conditions of diet In man the doses used were moderate, i e, 500 calories daily in the form of alcohol distributed in six portions With the animals a range of dosage leading to distinct intoxication was employed The findings in general were as follows There is no pronounced disturbance in the alimentary utilization of the foodstuffs Moderate doses exert a protein sparing action, which is succeeded by loss of nitrogen when larger quantities of alcohol are administered The partition of urinary nitrogen remains remarkably unaltered with the exception of an increased elimination of ammonia nitrogen (accompanying other evidences of perverted metabolism as indicated by the appearance of optically active (levorotatory) compounds in the urine, following "toxic" doses and a higher output of purins The theoretical significance of the latter which affects both the endogenous and exogenous fractions, is discussed at some length, and its bearing on the assumed nutrient properties of alcohol is indicated The most significant impression, perhaps, which the analytical data afford is the absence of pronounced alterations indicative of markedly disturbed protein metabolism, even when comparatively large doses are continued for days and weeks This has been interpreted as another evidence of the "factor of safety" in metabolism

67 **Isolated Kidney.**—A perfusion apparatus is described by Hooker which yields a pulsatile wave of pressure similar to the normal pulse wave and which allows of alteration in the magnitude of the pulse pressure The use of the apparatus in the study of isolated (dog's) kidneys yielded the following results With a constant mean perfusion pressure the amount of urinary filtrate varied directly as the magnitude of the pulse pressure With a constant mean perfusion pressure the amount of protein in the urinary filtrate varied inversely as the magnitude of the pulse pressure With a constant mean perfusion pressure, the rate of blood flow through the organs varied directly as the magnitude of the pulse pressure

69 **Secretion of the Infundibular Lobe**—The object of this communication is to call attention to the presence of a substance in the cerebrospinal fluid which gives the same reactions as extracts of the pars nervosa itself, indicating in all probability that the active principle long recognized as being confined to this anatomic subdivision of the gland is actually secreted into the ventricular cavity This would seem to establish the theory that the hyaline bodies of the pars nervosa, regarded by Herring as products of secretion of the posterior lobe——a view supported on experimental grounds by the authors—actually discharge as their histologic appearance suggests, into the third ventricle and represent the source of the active substance resembling pituitin in the cerebrospinal fluid

71 **Total Nitrogen Excretion of Kidney.**—The work done by the Barringers was carried out on eleven young men all in good health In collecting the urine the method of Albarran was employed As regards the total nitrogen in one case the quantities were equal In seven cases they varied by less than 1 gm to the liter In two cases they varied by between 1 and 2 gm to the liter The nitrogen urea plus ammonia-urea showed in three cases a variation of less than 1 gm to the liter and in six cases a variation of between 1 and 2 gm

74 **Metabolism of Development**—The nitrogen balance was followed by Murlin through two complete periods of gestation beginning with copulation, through parts of two others beginning several weeks previous to menstruation and through one period of menstruation which was not followed by copulation In the first two experiments the diet contained 70 calories and from 0 65 to 0 75 gm N. per kilogram daily From the first pregnancy one puppy was born, and the result was a net gain of 8 69 gm N to the mother's body From the second four puppies were born, and the result was a net loss of 55 6 gm. N from the mother's body. Up to the fourth week in these two experiments (on different dogs) the amounts of nitrogen lost from the mother's body were proportional to the weights of puppies delivered The effect of the menstruation was to cause a retention of nitrogen, which may be explained, in part at least, as a compensation for the amount of blood lost The results of these experiments, Murlin believes, support the idea that nitrogen loss from the mother's body is characteristic of the first half of normal pregnancy in the dog, particularly of the third and fourth weeks This is probably due to the action of proteolytic enzymes produced by the embryo and not yet limited by the placenta in their action to the maternal blood Nitrogen retention has been found in these, as in all other experiments, in the last half of the pregnancy The curve of nitrogen elimination in the urine shows that the retention in the last week of pregnancy is fairly even from hour to hour.

81 **Tuberculosis of the Body of the Uterus**—The author believes that his case is without any doubt one of tuberculosis of the uterus, originally of the myometrium That there was no affection of the ovaries, the tubes, the serous membrane, or the endometrium on the surface, excludes the primary localization in them as is the usual case On the other hand, the extension of tuberculous alteration in the muscle of the anterior wall toward the fundus in the form of a great caseous gumma surrounded on all sides by bands of muscles, and the diffuse caseous necrosis of the focus serve to demonstrate the original seat of the process, while the miliary tubercles scattered in the neighboring muscle and toward the mucous coat evidently indicate a more recent diffusion The localization in the myometrium, he thinks, must certainly have come by way of the blood-vessels, and probably is secondary to another focus in the organism, of which, however, clinically there was no trace, but it may exist if only in one or a few peribronchial or mesenteric ganglia without any actual symptomatic manifestation.

83 **Tumors of the Appendix.**—A study of the primary malignant growths of the appendix has convinced Crouse that the appendix should always be investigated while doing other intra-abdominal work; that many so-called spheroidal cell primary carcinomas of the appendix may be simply remains of imperfect tissue repair. Why, he asks, should the simple removal of an organ, an integral portion of a continuous structure, seemingly malignantly involved, give nearly an absolutely good prognosis in 57 per cent. of all malignant cases and 100 per cent. of the spheroidal type?

84 **Etiology of Cholecystitis.**—This work was undertaken by Else for the purpose of throwing more light on infection through the blood stream and to determine, if possible, which is responsible for the most cases of cholecystitis, the portal system or the general circulation. All work was done on rabbits, with the exception of two experiments quoted from a previous communication, and under strict aseptic and antiseptic precautions. The *Bacillus pyocyaneus* was used, as this organism is not present normally in the gall-bladder of the rabbit, and it is an organism that is easily identified. A ligature was placed about the cystic duct, care being taken not to include the cystic artery. One cubic centimeter of a virulent culture was injected into a superficial vein. Later, a culture was made from the gall-bladder. The ligature prevented the ascension of infection from below so that the bacilli could reach the gall bladder only through the cystic artery. Hence this series demonstrates that organisms in the general circulation reach the gall bladder readily through the terminal arteries and capillaries the same as they reach other organs. One cubic centimeter of the culture was next injected into the portal vein. Later, a culture was made from the gall bladder. This group of experiments showed that when organisms are injected into the portal vein they do not readily reach the gall bladder, but it does not show that they did not reach the bile, for they may have been carried on down the common duct instead of ascending the cystic duct into the gall bladder from whence the culture was made. In order to determine whether the organisms did reach the bile, the common duct was ligated and 1 cubic centimeter of the culture was injected into the portal vein. Later, cultures were made from the gall bladder. This group proves that when infection is injected into the portal vein it will reach the bile. There are two possible routes through which the infection may have gone, first, by passing through the capillaries from the portal vein to the hepatic veins, then through the general circulation to the gall tract, through branches of the hepatic artery, and second by passing from the capillaries through the normal liver cells into the bile radicals. Now if the cystic duct were ligated and infection injected into the portal vein, it would determine the route, for if it were by the general circulation the gall bladder would become infected, as the organisms would reach it through the cystic artery. On the other hand, if infection of the gall bladder be through the portal route, the contents of the gall bladder would be sterile, for with the cystic duct ligated there would be no way for the infection to reach it. Accordingly, the cystic duct was ligated, care being taken not to include the cystic artery. One cubic centimeter of the virulent culture was injected into the portal vein. Later, a culture was made from the gall bladder. This group proves that infection passes from the portal vein to the hepatic veins through the capillaries and thus reaches the gall bladder through the general circulation. And this series demonstrates, first, that infection of the gall bladder from the blood is through the arteries, and second, should infection reach the portal vein it is transmitted to the gall bladder through the general circulation.

87 **Blood-Supply of the Liver.**—The point Strehlin makes is that the commingling between the hepatic artery and portal vein is established through the medium of a tremendously ramified and interposed capillary system, and in consequence of which the circulation of the liver is very much retarded. In the case reported by him, the severance of the left hepatic artery shut off the blood supply of the left lobe of the liver completely. The effect was two fold: locally death to the entire lobe, since the hepatic artery is the nutrient vessel, and secondly, since the hemorrhage was tremendous, a lowering of the blood pressure sufficient to cause a voluntary arrest of the hemorrhage, yet was not sufficiently profuse to drain off enough blood to cause death. The hemorrhage from the parenchyma of the liver, though probably great, was arrested by the lowered blood pressure due to the arterial hemorrhage from the left hepatic artery, facilitated, *a priori*, by the lower blood pressure of the portal vein and hepatic vein. The anastomotic interchange of blood between the portal vein and hepatic vein would undoubtedly have led to a fatal termination, had both or either been severed, due to the close proximity of the vena cava, besides, the sparse supply of connective tissue and relatively poor supply of elastic fibers in the liver would have favored hemorrhage in spite of the lowered blood pressure. Hence, since the anastomosis occurs from the hepatic artery to the portal vein, and never in the reverse, and since the hepatic artery is a small vessel, and since the circulation in the liver is normally very much retarded and since the veins are devoid of contractile tissue, this is what happened. After rupture of the hepatic artery, the left lobe was drained and was no longer nourished. The blood pressure was reduced, causing an arrest in hemorrhage and a stasis at the areas of commingling with the hepatic artery and portal vein. The stasis led to the formation of thrombi in the radicles of the portal vein and hepatic vein.

88 **Surgery of the Thorax.**—In so far as Quinby's experimental observations go they confirm the experience of Meltzer, Carrel and Elsberg, who find that the method of intratracheal insufflation is very safe, and rests on a firm physiologic basis. In some thirty observations, some of them as long as four hours, others during such severe operations as total right pneumectomy and esophageal sutures, Quinby states that he has never had a death due to the method of anesthesia.

89 **Treatment of Postoperative Abdominal Adhesions.**—During the past three and a half years, Crump has introduced sterile oil into over 200 abdomens. In the majority of these cases, olive oil was the one employed. Many grades and kinds have been used owing to the fact that they had frequently to be obtained and prepared on the spur of the moment. After a careful study of the subsequent history of these oil cases, together with additional experience derived from its use in further cases, various points in which olive oil failed to fulfill all the requirements of a perfect menstruum gradually evolved. It was noted that normal surgical reaction was frequently more marked than in similar cases in which oil was not used. In a few cases, the oil seemed to fail in the prevention of postoperative adhesion (in two patients who subsequently had to be reoperated on, and in each of whom numerous adhesions were found), but, on the whole, it has been so gratifying in its minimization of the post operative sequelæ, especially adhesions, that Crump has come to believe that its use has marked a decided advance in surgery.

92 **Bone Transference.**—In McKenty's case, the diaphysis of the tibia was entirely absent except for a conical piece of bone at either end, one attached to the upper epiphysis with its point directly downward, and the other attached to the lower epiphysis with point directed upward, each piece being from 1½ to 2 inches long. So far as could be determined by palpation the intervening space of about 6 inches in length was devoid of osseous tissue. Just external to the original scar, an incision was made from the upper tibial epiphysis to the lower, the full length of the limb. Each conical stump was isolated and its point removed by saw, leaving a flat surface of a diameter about equal to that of the fibula. The fibula was then exposed and sawn through at points opposite to the ends of the stumps and the segment moved forcibly over into a sulcus prepared for it by a little blunt dissection. One silver wire suture held each end in apposition to the stump of the tibia. The wound was closed and the leg put up in a plaster cast. Healing occurred without complication. In September 1906, three months after operation, the man was able to walk on the leg. The final result is all that could be expected. The upper end of the transferred segment has been displaced outward and has formed the bony union with both tibia and fibula. Motion at the ankle joint is considerably less than normal.

94 **Modified Viscera Forceps.**—The holding portion of Schoenberg's forceps consists of rubber-covered incomplete rings, which permit rubber tubing to be put on or removed, when replacing becomes necessary The jaws of the forceps meet and lightly compress each other when closed at the first catch on the handle, and when closed to the third or fourth catch the hold is firm. Schoenberg says that these forceps may be made use of for catching and holding the tube, ovary, round ligament bowel, uterus, or any of the abdominal viscera without injury to the delicate peritoneum. It may be used to advantage in picking up an appendix through a small incision, or holding a bound down gangrenous appendix after slightly liberating it from its bed of adhesions Thus the appendix can be ligated and removed with greater ease through a smaller abdominal opening and when dealing with an acutely inflamed appendix or tube with less disturbance to the protective adhesions By the aid of these forceps, therefore, the intra-abdominal work can be done with greater ease, through a smaller opening, with less intra abdominal handling, and with no injury to the delicately covered structures.

95 **Peritoneal Director**—Church's peritoneal director consists of a flat spoon director with a handle at right angles so shaped that 3 inches of fat in the abdominal wall will not interfere with its being easily inserted and held in a proper position Its use is readily acquired After the initial incision is made in the peritoneum the director is inserted in the cut and pushed along the line of the proposed incision close to the under side of the peritoneum, which is cut rapidly with scissors or knife In sewing the peritoneum this instrument can be used for the same purposes as the Beck spoon, and acts better in fat subjects for it can be held level, which is impossible with the latter instrument The advantages of the peritoneal director may be stated briefly as follows· 1 It is safer than the usual method in enlarging the primary opening in the peritoneum 2 It saves time 3 It can be used to keep back intestines in closing the peritoneum

108. **Uterine Myomata.**—The technic which Frick employs differs in no essential particular from that described by Dr Howard Kelly. The abdominal cavity is walled off with gauze, the uterus delivered and protected with gauze wrung out of warm salt solution. Incision is made in a generally transverse direction over the most prominent part of the tumor The myoma is shelled out and the incision closed by a figure-of eight hemostatic suture of No 1 iodized catgut. This effectively controls the oozing The line of sutures is covered as well as possible with the uterine peritoneum or with a fold of the broad ligament if feasible, by Lembert suture of No 0 iodized catgut, the knots being buried as well as possible. This second line of sutures is important in reducing the danger of adhesions

119 **Cammidge Test in Experimental Pancreatitis.**—As a result of their experiments the authors conclude that the Cammidge test is of little value in establishing a diagnosis of acute pancreatitis in dogs. If the test is negative, it is pretty strong evidence against an acute pancreatitis. The Cammidge test is of even less value in the condition of chronic pancreatitis in dogs and may be consistently absent even in extreme grades of this disease. A positive Cammidge test is not infrequent in normal dogs and men. The Cammidge test is almost constantly present in chloroform poisoning in dogs—a condition in which there is extensive liver necrosis and cell autolysis The test may be present in cases of pneumonia or in any condition in which there is active cell destruction and autolysis The Cammidge test may be produced experimentally almost at will by intraperitoneal injections of hydrolytic cleavage products These split products may be prepared by boiling pneumonic lung tissue (dog or man), or thymus for hours with dilute acid, neutralizing, filtering and concentrating to a clear fluid. The melting point of the crystals varies under different conditions indicating that the substance or substances are not constant. The method is open to various errors and too much depends on the personal equation particularly in the interpretation of the various crystals.

3 **Strangulated Omental Hernia**—A man, aged 60, complained of griping pain all over the lower abdomen, the pain was general, not tender near the appendix Cressy found a large swelling in the lower inguinal region the size of a fist, solid and hard, tender and without impulse He cut down on the mass It was indurated and showed no landmarks Presently a black mass came into view, and slitting up the cavity in which it lay, he laid bare as much as three fingers of gangrenous omentum Freeing the internal ring, and passing his finger into the abdomen, he felt a large hard mass extending as far as the middle line like a sausage With difficulty freeing this he got it through the opening, and found that it was a mass of gangrenous omentum as big as two fists Having freed it all around, he ligated it off close to the bowel, the left testicle and cord were also removed

6 **Alcohol Vapor Mixed with Oxygen**—Willcox and Collingwood call attention to the remarkable stimulant effect on the heart and circulatory system produced by the inhalation of oxygen containing alcohol vapor When this combination is used, it can be readily demonstrated in cases of cardiac failure that the addition of alcohol vapor to the oxygen administered produces a stimulant effect on the circulatory system much greater than that produced by the breathing of oxygen alone. These are the good effects of the oxygen plus an additional marked stimulant effect on the circulation caused by the contained alcohol vapor Oxygen which had been bubbled through absolute alcohol contained in an ordinary wash bottle was administered in several cases of illness in which cardiac failure was a prominent symptom, and it was found that the mixture produced a marked stimulant effect on the heart and circulation, decidedly greater than that produced by oxygen alone In some of these cases the administration appeared to have been the cause of the prolongation and saving of life In cases of pneumonia with cardiac failure the mixture of oxygen and alcohol vapor was found to be a valuable remedy

7. **Pulmonary Thrombosis**—Glynn and Knowles have found that spontaneous thrombosis is much commoner than embolism, in the proportion of 8 to 1 in 1,200 post mortem examinations from a single hospital They believe that an unaccountable acceleration of the pulse or respiration rate, beginning in the second week after a major operation, especially abdominal, and associated with slight pyrexia, suggests the possibility of spontaneous thrombosis and of a sudden fatal termination about the third week Cases of spontaneous thrombosis are overlooked from the assumption that only embolism can cause death in a few minutes, from neglect to remove and harden the heart and lungs together, and trace the distribution of the thrombi *in situ* in properly hardened specimens, and especially from neglect to make a thorough microscopic examination Even the association of the pulmonary clots with others in the systemic veins does not necessarily prove that the former are embolic Both may have arisen spontaneously and separately from similar causes

8 **Distinguishing Dead from Live Leukocytes**—Achard reports some researches on the distinction which may be drawn between dead and living leukocytes by using neutral red Living leukocytes are uncolored, or contain red stained or intraprotoplasmic vacuoles or granulations. Dead leukocytes show their nuclei red brown, and no intraprotoplasmic coloration Two solutions are used the one is physiologic salt solution with 6 per 1,000 of sodium citrate, the other is a physiologic salt solution with 1 per 1,000 of neutral red Mix in a tube 10 drops of each solution and add 1 drop of blood, or from 1 to 4 drops of the sediment of a centrifugalized exudate containing white cells, the tube is placed in the incubator and kept at the temperature of 37 C for twenty minutes, then the liquid is examined in a glass cell, and the living and dead leukocytes are separately enumerated Achard says that in the circulating blood there are no dead leukocytes, even in the gravest diseases If occasionally a few dead leukocytes are seen, fresh preparations must be made again and examined within five minutes, in order to avoid accidental injuries of the white cells, then they generally yield no nuclear staining In various exudates dead leukocytes are not scarce, especially in cases of suppuration In abscesses, the number of dead leukocytes suddenly decreases after the incision In acute meningitis, it appears that the variations in the leukocytes are valuable for prognosis, their disappearance is a good sign, and their increase an unfavorable indicator The red staining of the nucleus is also observed in recently dead and not yet disintegrated cells Therefore, a few stained nuclei are found in old suppurations, for instance, in tuberculous empyema, among a great deal of indistinct leukocytic remains

12 **Action of Oleic Acid on Blood**—Rabbits repeatedly inoculated with soaps of oleic acid subcutaneously became anemic. Blood regeneration was defective, there was no clear evidence that blood destruction was excessive Rats fed with oleic acid showed no changes in the blood

13 **Hereditary Hemophilia.**—Twelve cases were investigated In all the coagulation of the blood was delayed In those individuals in whom the symptoms were most marked the blood took an hour or more to coagulate, in one case in which the tendency to prolong hemorrhage was less marked the coagulation time was thirty six minutes, and in the slight cases it was about fifteen minutes This delay in coagulation was the only pathologic factor constantly present, and is in itself sufficient to explain all the symptoms There are good grounds, therefore, for regarding it as the proximate cause The cause was looked for in connection with the calcium, the thrombokinase, or the prothrombin Various quantities of calcium were added to hemophilic plasma but no amount reduced the coagulation time to normal Calcium was, therefore, not the cause With various amounts of thrombokinase the same result was obtained except when very large quantities were added, when coagulation was almost instantaneous in both normal and hemophilic plasmas But with lesser amounts, even such as were sufficient greatly to accelerate the coagulation of normal plasma, the coagulation of the hemophilic plasma still took much longer than the normal Further, there was found to be as much thrombokinase in hemophilic serum as in normal serum, and as much could be extracted from hemophilic blood corpuscles as from normal corpuscles Thrombokinase was, therefore, not the cause There was no quantitative deficiency as regards the prothrombin in hemophilic plasma, but a qualitative difference was present, which showed itself in the unduly long time required by the hemophilic prothrombin to change into thrombin in the presence of calcium and thrombokinase That this fault in the prothrombin was the sole cause of the delay in coagulation was shown by the fact that very small quantities of normal prothrombin when added to hemophilic plasma reduced the coagulation time to the normal The cause of hemophilia is, therefore, says Addis an inherited peculiarity in the constitution of the prothrombin whereby its activation into thrombin is retarded.

14 **Altmann's Granules and Malignant Growths**—Excluding new growths originating in cells not normally containing Altmann's granules, Beckton says, absence of granules from all the essential cells of a new growth indicates malignancy Presence of Altmann's granules in all or nearly all the essential cells of a new growth, is usually associated with non malignancy or only with malignancy of a special kind or limited degree (thyroid, ovary) In a tumor, the diagnosis of

which lies between inflammation and sarcoma, presence of Altmann's granules indicates the former, absence the latter.

33 *Influence of Quinin and Morphin on Phagocytosis H L Smith

28 **Desmoid Tumors.**—According to Morison and Drummond there are certain tumors—desmoids—originating in the abdominal wall, chiefly in the upper half of the rectum muscle, but also in connection with the other muscles, which are of considerable clinical importance They are likely to be mistaken for growths in the abdomen, unless the possibility of their occurrence is remembered. Their association with pregnancy is so frequent as to constitute more than a coincidence Possibly traumatism, by muscle stretching or tearing, is of etiologic significance A firm, but not tender, sausage shaped tumor, possessed of some mobility, across, but not in the direction of the fibers of the relaxed muscle with which it appears to be associated becoming fixed when that muscle is made tense and occurring in a woman recently pregnant, is a desmoid tumor The treatment is to excise the growth at once, along with a free margin of the surrounding structure, including the peritoneum underlying it.

31. **Faradic Current in Aphonia.**—A study of two cases of aphonia has led Hernaman Johnson to form conclusions regarding the pathology and treatment of persistent post catarrhal aphonia The larynx is primarily a mechanical device for the production of vocal sounds, and depends for its proper functioning even more on the integrity of its muscles and nerves than on the healthiness of their covering. In chronic catarrh of this organ the muscles become secondarily affected, and the delicate terminals of the motor nerves in all probability undergo an inflammatory degeneration An acutely inflamed mucosa doubtless demands local sedative applications, and even when the trouble has become chronic, astringent sprays paintings etc can often play an important part. But the tendency in many chronic cases is for the mucous engorgement to disappear to a great extent, whereas the damage to the neuromuscular apparatus remains Under such circumstances it is unreasonable to expect a cure by the ordinary means On the other hand, improvement may be looked for from such measures of 'natural therapy" as produce benefit in similar pathologic conditions elsewhere, e. g. in the form of facial palsy which is the result of exposure to the cold Hernaman Johnson says that in treating paresis of laryngeal muscles by faradization, the secret of success lies in the regular and persistent use of mild currents, which are not calculated to produce violent contractions of opposing healthy muscles If carefully applied for a prolonged period this form of electricity exercises a selective action on the affected structures and eventually restores their tone. Remarkable as are the results in suitable cases, however, it must not be regarded as a panacea for each and every form of catarrhal aphonia When the laryngoscope shows marked swelling and congestion of the cords, the mucous membrane must be attacked vigorously on orthodox lines Nevertheless, even when the mucosa is the part most at fault, the judicious use of the interrupted current, he declares, forms a valuable adjunct to routine treatment

32. **Phlegmasia Alba Dolens.**—Five days after delivery, Curtis's patient developed phlegmasia alba dolens in the left leg. Under treatment she progressed favorably for seven days when she was seized with violent pains in the left chest and shortness of breath The respirations were 72, pulse, 108, regular, but very feeble; the temperature, 100 F. The extremities were cold She complained of intense pain over the epigastrium precordia, and lower axilla An impaired note was found over the lower part of the axilla, and the breath sounds over this area were badly transmitted; no friction sound was heard. A soft systolic murmur could be heard over the pulmonary area and the second sound was accentuated. She suffered from retching and some vomiting, and the smallest amounts of liquid nourishment caused great pain over the precordia and lower axilla. As the stomach was dilated this was attributed to pressure on the diaphragm, interfering with cardiac and respiratory movements. Hot water bottles were applied to the feet and hot applications to the chest. She was given iced milk and soda-water with brandy in small quantities at frequent intervals. She was also given the following mixture every four hours:

℞		gm or c c
Bismuth carbonate	gr x	65
Aromatic spirits of ammonia	m xv	1
Compound tincture of cardamoms	m x	60
Muscilage, q s, and water................	℥i	30

On the following day the vomiting had ceased The respirations were 66; pulse, 102, and temperature, 101 F. She still had considerable pain over the lower axilla, and a marked friction sound could be heard over this area It was noticed that the swelling in the left leg had diminished considerably; it was much softer and free from pain. The pulmonary systolic murmur could still be heard, although it was not so marked. Three days later there was a considerably impaired note over the lower half of the upper lobe, and the whole of the lower lobe and axilla, with marked tubular breathing, bronchophony and pectoriloquy. The temperature was 99 F., respiratory rate 60, and pulse 96, regular, and of medium tension. The pulmonary sounds were clear. There was good air entry at the base, but dulness persisted over the axilla, the lower half of the upper lobe, and the upper half of the lower lobe; and over these areas there were still tubular breathing, bronchophony and pectoriloquy. There was still an occasional dry cough but no expectoration. The temperature was normal. The left leg had resumed its normal size. The lung symptoms gradually cleared up.

33. **Influence of Quinin on Phagocytosis.**—Smith made a series of researches to ascertain, if possible, the truth of the statement that quinin, like alcohol in excess, inhibits phagocytosis, and is therefore contraindicated in septic conditions. The opsonic index was taken as a basis for the work, with the additional factor of a solution of quinin and morphia. The very soluble acid hydrochlorid of quinin was selected because it is much less irritating than the sulphate and contains 8 per cent more quinin Morphin hydrochlorid, 1/8 grain, was added to each 10 grains of the quinin salt. It was roughly calculated that a 10 grain dose given to a person weighing 140 pounds, if entirely absorbed, would represent in the blood a proportion of 1 to 7,500. The influence of this solution (1 to 7,500, equivalent to a 10-grain dose) on the phagocytosis of different kinds of pathogenic organisms (e. g., streptococci, staphylococci, pneumococci, *B. coli*, *B. influenzæ*, *B pseudodiphtheria*, and *B. tuberculosis*) was contrasted with stronger and weaker solutions to ascertain the effect of varying doses In the majority of the eleven sets of experiments, there was an increased phagocytosis, always most marked with the 10 grain dose solution. Instead of inhibiting phagocytosis, the addition of quinin and morphia, in what may be considered the 'ideal" dose, greatly increased it. Smaller doses in all the groups were less effective, and one important fact was clearly demonstrated—namely, that very large doses (30 and 40 grains), instead of increasing, actually diminished phagocytosis, sometimes to the extent of 50 per cent

41 *Non Cystic Ovarian Tumors M Mériel
42 *Stenosis of the Pylorus from Muscular Hypertrophy P Fredet and L Guillemot
43 *Megacolon M Patel

41 **Non-Cystic Ovarian Tumors** —Mériel discusses all kinds of ovarian tumors outside of cysts He has found only seventeen fatalities in the 289 operative cases on record since 1900, the mortality thus being from 4 to 1 5 per cent The percentage of permanent cures has been 15 per cent in the 372 cases compiled by Estor between 1881 and 1900 and the proportion is much higher in later series The figures show that the operative mortality is no higher when both ovaries and the uterus are removed The final outcome, he states, is much better for these non cystic ovarian tumors, especially the malignant, than with cancer of other genital organs or organs elsewhere This favorable prognosis includes both the operative and remote results, and it encourages early operation in case of a solid, movable tumor of the ovary As there is no reliable sign to differentiate the benign from the malignant tumors, there should be no delay; the abdomen once opened the surgeon can then decide whether to continue or abandon the operation Bilateral ovariotomy can be done without interrupting a pregnancy; after delivery the ovarian tumor should be removed without delaying for more than two or three days The favorable figures shown by the latest statistics permit more initiative than in the past Metzger has compiled 150 cases of ovarian cancer complicating gastric cancer, and Hartmann has reported a case in which he successfully removed a cancer in both ovaries and the primary cancer in the pylorus, the patient, a woman of 38, leaving the hospital in good condition, the operations were done in two sittings with a month's interval In Boeckel's case two large cancers were removed from the ovaries, necropsy a few months later disclosed an unsuspected cancer in the stomach

42 **Stenosis of the Pylorus in Infants from Muscular Hypertrophy.**—Fredet and Guillemot do not consider the anatomic lesion as necessarily entailing fatal impermeability, the superposed factors are the dangerous elements—the inflammatory swelling of the mucosa and spasm of the hypertrophied muscle which aggravate the stenosis These latter factors may be influenced by medical treatment, resting the stomach by feeding a teaspoonful at a time, merely iced boiled water at first, and combating the spasm by lavage, hydrotherapy and local heat The dietetic measures are the most important, the stomach will sometimes tolerate up to 5 gm of breast milk at a time These small amounts should be kept up for about two weeks and then the amount gradually increased The food with which he has been most successful is a milk gruel or malt soup Sedatives are given to reduce the tendency to spasm In the severe forms lavage may be useful but it sometimes aggravates the weakness, in one case it seemed to be responsible for the collapse observed In case operative treatment becomes necessary, partial pylorotomy by a straight longitudinal incision down to the mucosa, enables the muscular fibers to spread The lips of the longitudinal incision are then drawn apart and sutured together again to form a transverse line The two children on whom this technic has been applied recovered at once and are now healthy and well developed, Weber has reported two similar cases In 185 operations for this form of stenosis the immediate mortality was 47 per cent, but the mortality was only 26 31 per cent in the thirty eight cases in the last three years in which the operation was this partial pylorotomy Fredet and Guillemot warn especially against letting the child become chilled during the operation The outcome is immediately favorable in the children without existing gastro enteritis, but when this is present convalescence is a little retarded but not so much as might be expected Only two of the fifty three children operated on according to this preferred technic of posterior gastro enterostomy succumbed later to progressive debility

43 **Megacolon** —Patel gives a historical sketch of idiopathic dilatation of the large intestine or Hirschsprung's disease, and reviews 223 cases with an operation or necropsy, all but seventy three were in children. About 57 per cent. of the seventy four children operated on and 57 per cent of the forty one adults were cured by the operation His review shows that the mortality grows less as the children increase in years, under the age of 2 there were thirteen deaths for thirteen operations, some merely an exploratory laparotomy; from 2 to 5, only four of the fourteen children survived, but between the ages of 5 and 15 there were twenty seven recoveries to ten deaths and between 15 and 50 years of age there were twenty two recoveries to eight deaths, after the age of 50 only one recovery is reported to ten deaths He thinks that it is not enough to fasten or take up a fold in the colon, while resection is too serious, unilateral exclusion gives the best results from all points of view

Bulletin de l'Académie de Médecine, Paris

October 18 LXXIV, No 32, pp 197 220

44 *Paralysis of the Recurrent Laryngeal Nerve and Mitral Stenosis E Boinet

44 **Paralysis of the Recurrent Laryngeal Nerve and Mitral Stenosis** —Boinet reports two cases and discusses what has been published on this subject by Osler and others, all proving that recurrent paralysis is liable to accompany mitral stenosis, either from direct compression of the left recurrent nerve by the left auricle or by traction downward from the dilated and hypertrophied right ventricle or from both these factors This cause for the paralysis should be borne in mind after exclusion of the usual causes

45 *Spinal Anesthesia in Gynecology (Etude sur la rachistovainisation) Violet and Fisher
46 Operative Treatment in Cholelithiasis (Du choix de l intervention dans la lithiase biliaire) G Cotte
47 Traumatic Dislocation of the Scaphoid Bone in the Foot E Destot

45 **Spinal Anesthesia** —Violet and Fisher have compiled 30 000 cases from the literature to which they add 270 cases from Pollosson's gynecologic clinic, and discuss the special indications technic and results They regard raising the pelvis as decidedly dangerous at first, while the drug is diffusing, and this phase may last for twenty or thirty minutes The great danger of the spinal technic is the liability to stoppage of the respiration, this occurred twice in their 270 cases, but they were able to revive one of the patients In the fatal case necropsy disclosed an unsuspected pleural effusion which should have contraindicated general anesthesia, especially by the spinal technic Another fatality was evidently the direct result of lowering the patient's head too soon after the injection, some of the fluid had been lost in making the injection and the pelvis was raised at once The skin was incised seven minutes after the injection and the patient, an obese woman with cancer of the cervix uteri, stopped breathing and could not be revived They list further the details of thirty six other fatalities in European literature following injection of stovain, tropacocain, or novocain for spinal anesthesia In twenty cases the fatal syncope occurred within fifteen minutes and in others not until after several hours In four of the cases suppurative meningitis was evidently due to lack of asepsis in the technic In four other cases mechanical interference with the action of the lungs from an effusion was responsible for the fatality, in fourteen cases the cachexia or infection was already in a dangerously advanced stage In seven of the total thirty six fatalities the stovain must be directly incriminated they think Paralysis of legs or sphincters developed in sixteen cases, generally subsiding after a few days or months, but entailing fatal complications in bladder or kidney in two cases and fatal infection from an eschar in a third, while in three cases the paralysis or ataxia seems to be permanent Study of these cases shows a pre existing predisposition—syphilis or alcoholism—which should have contraindicated the method, or else the dosage was too large or asepsis violated The spinal method, the authors state, is particularly adapted for gynecologic operations, as the field is all in one plane innervated from the same segment of the spine; the relaxation of the muscles is complete, there is no vomiting; the operative shock is less than with other technics and there is no irritating action from the anesthetic on the lungs;

which lies between inflammation and sarcoma, presence of Altmann's granules indicates the former, absence the latter.
